INDEX TO VOLUME V.

The asterisk (*) denotes that the subject is illustrated.

- Abelia rupestris*.....329, 520
 serrata.....182
Abies balsamea, var.....274
 concolor.....274
Abutilon variegated, Eclipse.....116
 venillarium igneum.....428
Acacia dealbata.....341
 decurrens.....262
 Drummondii.....154
 Farnesiana.....580
 fragrans.....615
 melanoxylo.....263
 mollissima.....178
 Nemu.....15, 254
 pycnantha.....262
Acalypha tricolor.....536
Acampe Madagascariensis.....4
Acanthopanax ricinifolia.....183
Achillea Mongolica.....300
 the Pearl.....394
Aconitum autumnale.....464
Actinidia polygama.....320, 555
Ada Lehmanni.....30
Adiantum assimile.....308
 Capillus-Veneris imbricatum.....552
 magnificum.....464
 cuneatum grandiceps.....308
Adlumia cirrhosa.....297
Adonis vernalis.....236
Aërides Augustianum.....462
 Lawrenciæ Amesianum.....30
Æschynanthi, cultivation of.....558
Æsculus parviflora.....360
Agapanthus umbellatus.....460
Agricultural colleges, botany in.....593
Agriculture, Massachusetts Society for promoting.....371
Agrostis alba.....618
Ailanthus flavescens.....543
Alabama, mountain flora of.....597
Alaska, berries in.....384
Albemarle Pippin.....24
Alberta magna.....40
Allamanda cathartica.....428
 Hendersonii.....428
 nobilis.....162
 Schottii.....162, 428
 Williamsii.....40
Allen, C. L., article by.....501
Allium cernuum.....412
Almonds, flowering.....232
 in California.....351
Alphand, death of.....24
 monument to.....564
Alpinia nutans.....585
Alstroemeria aurantiaca.....354
 pelegriana alba.....512
Alternanthera, Leaf-blight of.....56
Althea ficifolia.....303
Alvord, Wm., paper by.....213, 237
Alyssum repens.....588
 saxatile.....236
Amaryllis Belladonna Kewense.....512
Amelanchier alnifolia.....493*
 Canadensis.....220
America, a foreigner's impressions of.....298, 309, 321
Amorphophallus Rivieri.....185
Ampelopsis quinquefolia.....400
 tricuspidata.....182
Anastatica hierochuntica.....506
André, Ed., paper by.....244
Andromeda Japonica.....543
Anemone blanda.....212
 robusta.....212
 Hepatica.....282
 Japonica.....92, 441, 620
 alba.....464
 Pennsylvanica.....295
 ranunculoides.....236
 Robinsoniana.....270, 284
 sylvestris.....260
 the Wind.....220
Angræcum fragrans.....30, 480
Annapolis, homes and gardens of.....599
Annals, garden.....488
 little-known.....416
Anthericum Liliastrum.....307
Anthracoze in bean-seeds.....18
 of the pear.....501
Anthurium Greyanum.....526
 Scherzerianum.....587
Aphelandra aurantiaca.....31
Apios tuberosa.....615
Appendicula Peyeriana.....76
Apple, Arkansas Black.....11
 Bailey Sweet.....11
 Cogswell.....11
 Fameuse.....176
 Ontario.....504
 Pelouse.....11
 Princess Louise.....11
 stocks, hardy.....16
Apple-leaf blight.....490, 526
Apples, Canadian.....176
 cider.....552
 cultivation in Kansas.....622
 in North Carolina.....48
 in the north-west.....131
 late-keeping.....80
 new.....180
 rare varieties of.....11
 scab-proof.....442, 467, 489, 514
 top-grafting.....558
Aquatic garden at Clifton, N. J. 310, 494*
 plant, a new.....280
 plants at Farview, Staten Island.....82
 cultivation of.....177, 283, 320, 332, 354, 404, 418, 439, 441, 477
 in California.....611
 in Central Park.....456
 in southern New Jersey.....363
 winter-flowering.....44
Aquilegia Canadensis.....272, 300
 chrysantha.....296
 Stuartii.....248
Arachnanthe Cathcartii.....153
Aralia Sieboldii.....596
Araucaria excelsa.....215
 imbricata.....82, 603
Arbor day.....169
Arboretum at Kew.....602
Arbutus Menziesii.....146, 238
 trailing, transplanting the.....202
Architects' gardens.....467
Architecture of gardens and green-houses.....612
Arctium Lappa Japonicum.....419
Ardisia crenulata.....165, 596
Aristolochia Gigas.....510
 Sturtevantii.....40, 400
 grandiflora.....510
 Serpentaria.....376
 Sipho.....509*
 tomentosa.....509
Armeria vulgaris.....332
Armeria, cultivation of.....9
Arnica nudicaulis.....220
Arnold Arboretum, notes from.....225, 249, 255, 282, 294, 318, 330, 343, 353, 367, 390, 402, 426, 571, 578, 580
 the.....27
Artemisia vallesiaca.....160
Asarum Virginicum.....110
Asclepias tuberosa.....402
Ascyrum Crux-Andree.....256*, 287
Ash, American, species of.....286
Asparagus plumosus.....43
 tenuissimus.....43
Aspidistra elatior.....596
Asplenium montanum.....117, 521
Aster alpinus.....308
 amellus.....521
 amethystinus.....377*
 Candelabra.....417
 corymbosus.....404
 diplostephioides.....521
 Herveyi.....404
 laevis.....521
 Lindleyanus.....404
 longifolius.....521
 macrophyllus.....404
 Novæ-Angliæ.....404
 Novi-Belgii.....404
 oblongifolius.....520
 paniculatus.....521
 ptarmicoides.....404
 sericeus.....472*
 Stracheyi.....521
 surculosus.....520*
Aster, Thomsoni.....521
Astericus pygmaeus.....506
Asters in English gardens.....520
 perennial.....453
Astragalus.....172
 Monspessulanus.....332
Athyrium Goringianum pictum.....464
Aubrietia Leichtlini.....272
Aubrietias, cultivation of.....272
Audubon, monument to.....528
Auriculas, cultivation of.....9, 211, 212
Australian plants in Kew.....222
Autumn-blooming perennial plants.....464
 foliage.....70, 603
 work in the garden.....441
Ayres, H. B., papers by.....297, 345
Azalea calyciflora.....150
 cuttings.....320
 Indica.....186
 Hexe.....408
Azaleas at Knap Hill.....305

B

- Baccharis halmifolia*.....154
 pilularis.....323
Bachelor's Button.....272
Bailey, Colonel, papers by.....356, 369
 Prof. L. H., articles by.....90, 310, 346, 398, 423, 442, 458, 470, 490, 514, 526, 587
 papers by.....2, 38, 50, 495, 518
Balamaacanda Chinensis.....440
Balsam, Large-cone.....274
Bamboo sheeting.....396
Bamboos, Japanese.....368
 garden.....174
Barberry, the Texas.....580, 611
Bark and bark products.....468
 beetles.....396
Barker, M., articles by.....8, 31, 92, 128, 162, 165, 272, 273, 284, 295, 298, 403, 415, 428, 491, 500, 523, 525, 560, 572, 585, 597, 609
Basket-plants for conservatories.....558
 for window culture.....572
Bassett, Wm. F., articles by.....21, 82, 188, 235
Bauhinia Galpini.....40
Baxter, Sylvester, articles by.....62, 134, 158, 374, 386, 411
Bay-tree.....238
Beach, Prof. S. A., articles by.....153, 513, 514
Beal, Prof. W. J., article by.....434
Bean, Japanese Soy.....60
Beans, bacterial diseases of.....620*
 experiments in crossing.....33
Bear Meadows, Pennsylvania.....314*

White Pines.

OF the true White Pines, a natural group, so called probably from the color of the wood the different species yield, and always easily recognized by the arrangement of their leaves in clusters of fives, surrounded by loose deciduous sheaths and by their thin cone-scales, six of the eleven or twelve species inhabit the territory of the United States, where, indeed, so rich is the composition of our forests, are found fully one-half of all the different Pines now known to exist. The type of the White Pines is the tree universally known in all the eastern and northern states by that name. It is the most valuable timber-tree of the region it inhabits, and no other tree, perhaps, has ever played such an important part in the material development of a country. It has brought cities and railroads and great fleets into existence, and far and wide over this broad land has furnished employment to tens of thousands of laborers and supplied material with which countless homes have been built.

Europe possesses a single White Pine, a rather unimportant tree confined to the mountain regions of Albania and Macedonia, and botanically not unlike the White Pine of the Himalayas, *Pinus excelsa*, a noble tree, attaining sometimes the height of a hundred and fifty feet, and an important element in the coniferous forests of Butan and the upper valley of the Indus. The forests of Japan and the other islands of the north Pacific contain two or three White Pines, but these are small trees of no great economic importance, although the picturesque *Pinus parviflora* is one of the handsomest and most satisfactory of the smaller exotic Pines which can be grown in our northern gardens.

But the centre of distribution of the White Pines is western America, where they occur in half a dozen different forms from British Columbia to central Mexico. The greatest of them all, and the noblest of all the Pine race, *Pinus Lambertiana*, or, as it is popularly called, the Sugar Pine,

disputes with the Sequoias the honor of being the largest of American trees, and on the seaward slopes of the Sierras rises not infrequently to the prodigious height of three hundred feet, spreading far and wide its great branches, in autumn pendulous under the weight of its superb cones. The Sugar Pine, which does not range far above the northern borders of California, is a southern tree, and at the north is replaced by a species of less stately habit, but of tougher constitution and wider range. This is the White Pine of Montana and Idaho, where this tree, the *Pinus Monticola* of botanists, seems most at home, although it reaches the coast of British Columbia and ranges south along the Cascade and Sierra ranges to central California, where it reaches an elevation of 10,000 feet. At the north, in sheltered cañons and near the margins of streams, *Pinus Monticola* becomes a noble and stately tree, sending up a tall stout shaft five or six feet in diameter, and more than a hundred feet in height. In less-favored situations it grows less vigorously, and in California, on the summits of the wind-swept Sierras, it is low, gnarled and contorted, and never very abundant, but, like most alpine trees, grows in isolated situations, as shelter has made it possible for seedlings to struggle slowly to old age.

The appearance of the mountain White Pine as it grows at great elevations in California almost at the southern limits of its range, and the general appearance of the vegetation on the summits of the high mountains of California, are shown in the two illustrations which appear in this issue, pages 5 and 7. They are from photographs made by Dr. W. H. Rollins, of Boston, on the slopes above the Yosemite Valley, and we are indebted to his courtesy for permission to reproduce them.

In general appearance the western White Pine has a strong resemblance to its eastern relative, although the branches are stouter and are inclined to grow in an upright direction, giving the young trees a narrow pyramidal habit. The color of the foliage and the character of the bark of the two trees are very much alike, although the western species can always be distinguished from the eastern by its much larger cones, sometimes eight or nine inches long, and by its more rigid and less serrulate leaves. Of the conifers of western America none is more hardy or grows more satisfactorily in the eastern states, with the exception always of three or four species of Colorado, and of the western Pines it is the only one which up to this time has really succeeded in this part of the country, where several fair specimens large enough to produce their cones every year can now be seen—interesting objects to the student of trees, but hardly distinct enough from our own White Pine to fix the attention of the casual observer.

As a timber-tree in some parts of Montana and in the Cœur d'Alène and Bitter Root regions of Idaho *Pinus Monticola* is of great value, furnishing as it does the only high-grade soft lumber produced there, although, unfortunately, the rapidly growing population of the north-west is fast exterminating all the accessible and all the large trees, which are manufactured into lumber but little inferior to the best eastern white pine.

Of the other White Pines which inhabit the territory of the United States *Pinus flexilis* is scattered on high mountain-slopes from western Texas to northern Montana, and to Arizona, Utah, Nevada and south-eastern California. It is usually a small stunted alpine tree comparatively rare at the south but forming open forests on the eastern slopes of the Rocky Mountains of Montana, where it is low and round-topped and the prevailing tree; and on some of the mountain-ranges of central Nevada, growing tall and shapely and furnishing the best lumber of the region; although, perhaps, it would be more correct to say that twenty years ago it furnished the best lumber found in the Great Basin; for the mining camps and the railroads have already exterminated the Nevada Pine-forests as sources of lumber-supply.

On the high mountains of the north-west *Pinus flexilis* is replaced by another White Pine which much resembles it

except in the brilliant white bark which covers its old trunks, and in its shorter cones with thicker scales. This is the *Pinus albicaulis*, a low, stunted alpine tree of much picturesque beauty as it appears at the edge of the timberline on Mount Shasta in California, but too small, scattered and inaccessible to be of any economic value.

Pinus Ayacahuite, a noble timber-tree, and the common White Pine of northern Mexico, where it forms extensive forests on high mountain-slopes, in a small cone-form grows on a few of the ranges of southern Arizona. Related to this species, and often confounded with it, is a second Mexican Pine and the last of our list of American White Pines, *Pinus Bonapartei*, a tree of whose distribution and value very little is known.

A CORRESPONDENT writes us from a village where an energetic Improvement Society was established last spring: "I'm afraid our people are overdoing the matter of tree-planting. Every member seems to feel that it is incumbent upon him to plant a tree somewhere, and usually a good many. The work is not done with much care or system, and I feel half-inclined to protest; but so zealous are the workers that I would probably be set down as an outlaw if I objected. May I inquire whether you would ever consider it advisable to 'discourage the planting of trees?' No one should ever plant a tree unless he is able to give a good reason why it should stand in the place selected, and unless he can tell why the tree he has chosen is preferable to one of any other species for the spot. No tree of any kind should be planted anywhere unless it is a healthy, vigorous individual, and unless there is reasonable assurance that it will be properly cared for in after-years. Professor Beal has told us that of twelve memorial trees planted with some official ceremony in Ann Arbor, not one was found to have made satisfactory growth two years later; only one had received any cultivation—nearly all were having an unequal struggle with grass, insects and poorly prepared or thin and hungry soil. Tree-planting of this sort is worse than a waste of time. Such an example is bad in every way, discouraging, demoralizing.

It is not an uncommon complaint among the newly organized associations for village improvement that the zeal of its members finds an outlet in excessive tree-planting. It is an easy thing to put the roots of a tree in the ground, and then have it to look at with complacency as a monument of our public spirit. The watchful care which ought to follow, however, requires an unwavering determination, patience and study which do not always follow sudden spurts of devotion to some popular movement, and the trees languish. What is worse, the planters often look on themselves with great approbation for what they have done, and neglect to do anything else. One of the very best societies of this sort in New England passed through this experience, although the village now enjoys thorough sanitary drainage, clean, well-sprinkled and well-lighted streets, sidewalks kept in good repair, neat hitching-posts and public watering-trough, and a general trimness and tidiness which are the direct outcome of the work of this organization. All this necessary work was postponed, and the united energy of the reformers was devoted to planting trees, until so many had been set out that the removal of a considerable portion of them became one of the plainest necessities in the improvement of the village.

It is too often the case that those who have determined to plant trees begin by studying descriptions in nursery catalogues, and select a motley list of those which promise to show some striking departure from those with which they are familiar. They then wait until late planting-time and send their orders; and after the trees have come they begin to search about for a place to put them. If it happens that too many have been ordered, or that few of them are adapted to the position selected, they are hurried into the ground and huddled together, and in a few years they are objects of pity rather than of admiration.

Crosses and Crossing of Plants.

THIS was the subject of a paper read at the late meeting of the Massachusetts State Board of Agriculture by Professor L. H. Bailey, of Cornell University. The paper is too long to reproduce entire, but we give in a condensed form what seems to us the most instructive part of the argument. Professor Bailey's language is adhered to in the main, but in some cases a paragraph is summarized in a sentence, and in this way the original loses some of its richness of illustration.

Sex clearly has two offices: (1) To hand over, by some mysterious process, the complex organization of the parent to the offspring; and (2) to unite the essential characters or tendencies of two beings into one. The second office is the greater, for it insures an offspring somewhat unlike either parent, and therefore better fitted to seize upon any place or condition new to its kind. And as the generations increase, the tendency to variation in the offspring must be constantly greater, because the impressions of a greater number of ancestors are transmitted to it. If, therefore, the philosophy of sex is to promote variation by the union of different individuals, it must follow that greatest variation must come from parents considerably unlike each other in their minor characters. Thus it comes that in-breeding tends to weaken a type, and cross-breeding tends to strengthen it.

In this discussion the term "cross" is used to denote the offspring of any sexual union between plants, whether of different species or varieties, or even different flowers upon the same plant. There are different kinds of crosses. One of these is the hybrid, or a cross between two species, as a Plum and a Peach, or a Raspberry and a Blackberry. Crosses between varieties of one species are termed "half-breeds" or "cross-breeds," and those between different flowers upon the same plant are called "individual crosses." Distinct species, however, as a rule, refuse to cross. If we apply the pollen of a Hubbard Squash to the flower of the common field Pumpkin, the fruit will not form. The same is true of the Pear and the Apple, the Oat and the Wheat, and most very unlike species. Or the pollen may "take" and the seeds may grow, but the plants which they produce may be wholly barren, sometimes even refusing to produce either flowers or seeds, as in the instance of some hybrids between the Wild Goose Plum and the Peach. Sometimes the refusal to cross is due to some difference in the time of blooming, or some incompatibility in the structure of the flowers. But it is enough to know that there are characters in widely dissimilar plants which prevent intercrossing, and that these characters are just as positive as are size, color, productiveness and other characters. That is, the checks to crossing have been developed through the principle of universal variability and natural selection, just as other characters have been established. The result is simply that the best results of crossing are obtained when the cross is made between different individuals of the same variety, or, at farthest, between different individuals of the same species. In other words, hybrids—or crosses between species—are rarely useful, and it follows, as a logical result, that the more unlike the species the less useful will be the hybrids.

Again, crossing alone can accomplish little. The chief power in the progression of plants appears to be selection. Selection is the force which augments, develops and fixes types. Man must not only practice a judicious selection of parents from which the cross is to come, but he must constantly select the best from among the crosses, in order to maintain a high degree of usefulness and to make any advancement; and it sometimes happens that the selection is much more important to the cultivator than the crossing. I do not wish to discourage the crossing of plants, but I do desire to dispel the illusion which too often hangs about it.

CROSSING STRENGTHENS EXISTING TYPES.

The improvement of existing varieties by crossing is a more important office than the summary production of new varieties. This is the chief use which nature makes of crossing—to strengthen the type. Think, for instance, of the great rarity of hybrids or pronounced crosses in nature! No doubt all the authentic cases on record could be entered in one or two volumes, but a list of all the individual plants of the world could not be compressed into ten thousand volumes. There are a few genera, in which the species are not well defined or in which some character of inflorescence favors promiscuous crossing, in which hybrids are conspicuous; but even here the number of individual hybrids is very small in comparison

to the whole number of individuals. That is, the hybrids are rare, while the parents may be common.

Darwin was the first to show that crossing within the limits of the species or variety results in a constant revitalizing of the offspring, and that this is the particular ultimate function of the operation. Darwin's results are, concisely, these: self-fertilization tends to weaken the offspring; crossing between different plants of the same variety gives stronger and more productive offspring than arises from self-fertilization; crossing between stocks of the same variety grown in different places, or under different conditions, gives better offspring than crossing between different plants grown in the same place or under similar conditions; and his researches have also shown that, as a rule, flowers are so constructed as to favor cross-fertilization. In short, he found, as he expressed it, that "nature abhors perpetual self-fertilization." Darwin's well-known experiments show that crosses between fresh stock of the same variety were nearly thirty per cent. more vigorous than crosses between plants grown side by side for some time, and over forty-four per cent. more vigorous than plants from self-fertilized seeds. On the other hand, experiments showed that crosses between different flowers upon the same plant gave actually poorer results than offspring of self-fertilized flowers. It is evident, from all his experiments, that nature desires crosses between plants, and, if possible, between plants grown under somewhat different conditions.

In extended experiments of my own in the crossing of Pumpkins, Squashes and Gourds, carried on during several years, increase in productiveness due to crossing has been marked in many instances. Marked increase in productiveness has been obtained from Tomato crosses, even when no other results of crossing could be seen.

NEW CHARACTERS FITTED TO NEW CONDITIONS.

Almost every farmer and gardener at the present day feels that an occasional change of seed results in better crops. Much of the rapid improvement in fruits and vegetables in recent years is due to the practice of buying plants and seeds so largely of dealers, by means of which the stock is often changed. Even a slight change, as between farms or neighboring villages, sometimes produces more vigorous plants and often more fruitful ones. In the cross, a new combination of characters or a new power fits it to live better than its parents in the conditions under which they lived. In the case of change of stock we find just the reverse, which, however, amounts to the same thing, that the new characters or powers fit the plant to live better in conditions new to it than plants which have long lived in those conditions. In either case the good comes from the fitting together of new characters or powers and new environments.

Crossing within the variety and change of stock within ordinary bounds are therefore beneficial, and the results in the two cases seem to flow from essentially the same causes, and crossing and change of stock combined give much better results than either one alone. These processes are much more important than any mere groping after new varieties, not only because they are surer, but because they are universal and necessary means of maintaining and improving both wild and cultivated plants. Upon this point Darwin expressed himself as follows: "It is a common practice with horticulturists to obtain seeds from another place having a very different soil, so as to avoid raising plants for a long succession of generations under the same conditions; but with all the species which freely intercross by the aid of insects or the wind, it would be an incomparably better plan to obtain seeds of the required variety, which had been raised for some generations under as different conditions as possible, and sow them in alternate rows with seeds matured in the old garden. The two stocks would then intercross with a thorough blending of their whole organizations, and with no loss of purity to the variety; and this would yield far more favorable results than a mere change of seeds."

PRODUCING NEW PLANTS.

The second result of crossing, the summary production of new varieties, is the subject which is almost universally associated with crossing in the popular mind, and even among horticulturists themselves. It is the commonest notion that the desirable characters of given parents can be definitely combined in a pronounced cross or hybrid. There are two or three philosophical reasons which somewhat oppose this doctrine, and which we will do well to consider at the outset. In the first place, nature is opposed to hybrids, for species have been bred away from each other in the ability to cross. If, therefore, there is no advantage for nature to hybridize, we

may suppose that there would be none for man; and there would be no advantage for man did he not place the plant under conditions different from nature or desire a different set of characters. We can overcome the refusal to cross in many cases by bringing the plant under cultivation where new conditions overpower its former antipathies. Yet it is doubtful if such a plant will ever acquire a complete willingness to cross. In like manner we can overcome in a measure the comparative seedlessness of hybrids, but it is very doubtful if we can ever make such hybrids completely fruitful. It would appear, therefore, that with plants in which fruits or seeds are the parts sought, no good can be expected, as a rule, from hybridization, and this seems to be affirmed by facts. It is evident that species which have been bred away from each other in a given locality will have more opposed qualities than similar species which have arisen quite independently in places remote from each other. In the one case the species have struggled with each other until each one has attained to a degree of divergence which allows it to persist, while in the other case there has been no struggle between the species, but similar conditions have brought about similar results. These similar species which appear independently of each other in different places are called representative species. Islands remote from each other, but similarly situated with reference to climate, very often contain such species, and the same may be said of other regions much like each other. Now it follows that if representative species are less opposed than others, they are more likely to hybridize with good results; and this fact is well illustrated in the Kieffer and allied Pears, which are hybrids between representative species of Europe and Japan. We will also recall that the hybrid Grapes which have so far proved most valuable are those obtained by Rogers between the American *Vitis Labrusca* and the European Wine Grape, and that the attempts of Haskell and others to hybridize associated species of native Grapes have given, at best, only indifferent results.

HYBRIDS RARE AND UNSTABLE.

Another theoretical point borne out by practice is that because of the great differences between parents, pronounced hybrid offspring are unstable. Again, because of the unequal and unknown powers of the parents, we can never predict what characters will appear in the hybrids. This fact was well expressed by Lindley a half century ago in the phrase, "Hybridizing is a game of chance played between man and plants." The characters of hybrids as compared with the characters of simple crosses between stocks of the same variety are therefore ambiguous, negative and often prejudicial.

The difficulties in the way of successful results through hybridization are, therefore, the difficulty of effecting the cross, infertility, instability, variability, and often weakness and monstrosity of the hybrids, and the absolute impossibility of predicting results. The advantage to be derived from a successful hybridization is the securing in combination the most desirable features of both parents; and this advantage is often of so great moment that it is worth while to experiment in the face of numerous failures. From theoretical considerations it is apparent that hybridization is essentially an empirical subject, and the results are such as fall under the common denomination of chance. And as it does not rest upon any legitimate function in nature, we can understand that it will always be difficult to codify laws upon it.

Among the various characters of hybrid-offspring, the most prejudicial one is their instability; it is difficult to fix any particular form which we may secure in the first generation of hybrids; and, therefore, we find that the great majority of the best hybrids in cultivation are increased by bud-propagation, as cuttings, layers, suckers, buds or grafts. In fact, there are few instances of undoubted hybrids which are propagated with practical certainty by means of seeds.

This simply means that it is difficult to fix hybrids so that they will come "true to seed," and makes apparent the fact that if we desire hybrids we must expect to propagate them by means of buds.

Let us now recall how many undoubted hybrids there are, named and known, among our fruits and vegetables. In Grapes there are the most. There are Rogers' hybrids, like Agawam, Lindley, Wilder, Salem and Barry; and there is some reason for supposing that Delaware, Catawba and other varieties are of hybrid origin. And many hybrids have come to notice lately through the work of Munson and others. But it must be remembered that Grapes are naturally exceedingly variable, and the specific limits are not well known, and that hybridization among them lacks much of that definiteness which ordinarily attaches to the subject. In Pears there is the

Kieffer class. In Apples, Peaches, Plums, Cherries, Gooseberries, Blackberries, Dewberries, there are no commercial hybrids. The Strawberry is doubtful. Some of the Raspberries, like Caroline and Shaffer, appear to be hybrids between the red and black species. Hybrids have been produced between the Raspberry and Blackberry by two or three persons, but they possess no promise of economical results. Among all the list of garden vegetables—plants which are propagated by seed—I do not know of a single authentic hybrid, and the same is true of Wheat—unless the Carman Wheat-Rye varieties become prominent—Oats, the Grasses, and other farm crops. But among ornamental plants there are many; and it is a significant fact that the most numerous, most marked, and most successful hybrids occur in the plants most carefully cultivated and protected—those, in other words, which are farthest removed from all untoward circumstances and an independent position. This is nowhere so well illustrated as in the case of cultivated Orchids, in which hybridization has played no end of freaks, and in which, also, every individual plant is nursed and coddled. For such plants the struggle for existence is reduced to its lowest terms; for it must be borne in mind that even in the garden plants must fight severely for a chance to live, and even then only the very best can persist or are even allowed to try.

POPULAR MISCONCEPTIONS.

This list of hybrids is much more meagre than most catalogues and trade-lists would have us believe, but it is approximately near the truth. It is, of course, equivalent to saying that most of the so-called hybrid fruits and vegetables are myths. There is everywhere a misconception of what a hybrid is, and how it comes to exist; and yet, perhaps because of this indefinite knowledge, there is a wide-spread feeling that a hybrid is necessarily good, while the presumption is directly the opposite.

There is an old yet common notion that there is some peculiar influence exerted by each sex in the parentage of hybrids. It was held by certain early observers, of whom the great Linnaeus was one, that the female parent determines the constitution of the hybrid, while the male parent gives the external attributes, as form, size and color. The accumulated experience of nearly a century and a half appears to contradict this proposition. There are instances, to be sure, in which this old idea is affirmed, but there are others in which it is contradicted. The truth appears to be, that the parent of greater strength or virility makes the stronger impression upon the hybrids, whether it is the staminate or pistillate parent. And it appears to be equally true that it is usually impossible to determine beforehand which parent is the stronger. The common little pear-shaped gourd will impress itself more strongly upon crosses than any of the edible squashes and pumpkins with which it will effect a cross, whether it is used as male or female parents. Even the imposing and ubiquitous great field-pumpkin is overpowered by the little gourd. Seeds from a large and sleek pumpkin, which had been fertilized by gourd pollen, produced gourds and small hard-shelled globular fruits which were entirely inedible. A more interesting experiment with the handsome green-striped Bergen Fall Squash showed a similar prepotency of the gourd.

Uncertainty follows hybridization, and uncertainty also attaches to the mere act of pollination. Between some species, which are closely allied and have large and strong flowers, four-fifths of the attempts at cross-pollination may be successful, but such a large proportion of successes is not common. Even the most expert operators fail as often as they succeed in promiscuous pollinating. In my own experience 234 pollinations of Gourds, Pumpkins and Squashes, mostly between varieties of one species and including some individual pollinations, gave 117 failures and 117 successes. But from all the 117 fruits, for some of them turned out to be seedless, and some were destroyed by insects before they were ripe or were lost by accidental means, a few more than half of the successful pollinations—if by success we mean the formation and growth of fruit—really secured us seeds, or but one-fourth of the whole number of efforts, and this was considered a successful experiment. Referring to a record-book where experiments were made with many species, I find that a total of 312 efforts resulted in 89 successes, 223 failures.

And now the sum of it all is this: Encourage in every way crosses within the limits of the variety and in connection with change of stock, expecting increase in vigor and productiveness. Hybridize, if you are curious to know what nature will do about it, but do it carefully, honestly, thoroughly, and do not expect too much. Extend Darwin's famous proposition to read like this: Nature abhors both perpetual self-fertilization and hybridization.

New or Little-known Plants.

New Orchids.

ACAMPE MADAGASCARIENSIS, Kränzlin.—A small species introduced from Madagascar by Messrs. F. Sander & Co., of St. Albans. It is a Vanda-like plant, with thick leathery leaves, and a short capitate raceme of whitish flowers, with the lip of a faint rose-purple tinge. It appears to be distinct from *A. Renschiana*, Rehb. f., and is thus the second species of the genus from Madagascar.—*Gardeners' Chronicle*, November 21st, p. 608.

DENDROBIUM × *LEEANUM*, O'Brien.—A handsome species, introduced *Denrobium Phalaenopsis*, from New Guinea, by Messrs. F. Sander & Co., of St. Albans. It is allied to *D. superbiens*, Lindl., but differs in various particulars, notably in the larger, more open labellum, and narrower acute petals. The sepals are white at the base, freckled with rose above, while the petals are bright rosy crimson. The lip is green at the base, with radiating reddish lines, the front lobe and margins of the side lobes being of a rich rosy crimson. The pseudo-bulbs are three feet long. It was awarded a first-class certificate by the Royal Horticultural Society on November 10th last.—*Gardeners' Chronicle*, November 28th, pp. 640, 641 (t. 88).

CORYANTHES LEUCOCORYS, Rolfe.—A handsome large-flowered *Coryanthes*, introduced from Peru by Messrs. Linden, L'Horticulture Internationale, Parc Leopold, Brussels, with whom it flowered during June last. The bucket-shaped part of the lip is of a beautiful rose-color, and the helmet pure ivory-white, thus forming a very handsome contrast. The sepals are striped and suffused with light brownish purple on a pale yellowish green ground, and the petals marked with light purple on a white ground. It is very distinct from every other known species.—*Lindenia* (t. 293).

CYCNOCHE PERUVIANUM, Rolfe.—An interesting species from Peru, introduced by Messrs. Linden, L'Horticulture Internationale, Brussels, with whom it flowered during May last. The male flowers only are at present known, and these are closely allied to the corresponding sex of the Mexican *C. ventricosum*, though quite different in color. They are light green, with numerous small brown spots, and a white lip, and are borne in a long pendulous raceme.—*Lindenia* (t. 301).

London Letter.

THE FRUIT MARKET.—We hear on all sides of a glut in the English market of almost all kinds of fruits. It is one of the peculiarities of this country that, while the market wholesale prices of fruit and vegetables may be so low that they scarcely pay the cost of carriage and packing, the consumer is compelled to pay the usual fancy prices. English garden-produce has to pass through too many hands before it reaches the mouth. I priced to-day in Covent Garden market American apples, Gravensteins and Baldwins and Ribstons; they were from twenty shillings to thirty shillings per barrel; grapes, fit to eat, were labeled four shillings per pound; pears, not absolutely rotten at the core, threepence each, and so on. Then I read in my morning papers of "a glut of apples in the market, the Canadian crop alone being estimated at a million barrels." But if I wish to purchase one of these barrels I must pay from twenty to thirty shillings for it. A few weeks ago I was informed by a market grower of grapes that he had houses full of good grapes, for which he would be glad to get anything over a shilling a pound, grapes, too, which I should have to pay four shillings for. Possibly you manage these things better in America than we do here. It is a mystery to me how growers for market get a respectable living out of their produce in this country. Yet a considerable number of them are unmistakably prosperous. The best market-grape in England is Gros Colman, of which there must be hundreds of tons grown in England alone.

Fig. 1.—*Pinus Monticola* on the Californian Sierra.—See page 1.

It looks well, keeps well, and is very easy to grow, while as a cropper it has no equal. The favorite white grape here is Muscat of Alexandria, which is almost as good all round as Gros Colman. The king of apples here is Cox's Orange Pippin. It has a handsome skin, packed full of good meat; it keeps well and fetches a good price; at any rate I was asked threepence a piece for apples of this sort a few days ago.

LUCULIAS.—A tall shapely specimen of *L. gratissima*, bearing five or six dozen large heads of its handsome fragrant flowers, is now an attraction in a warm conservatory at Kew, while near by a smaller specimen of *L. Pinceana*, also in bloom, serves to show the difference between these two. *Luculia* is an old garden genus; at any rate, it has been in cultivation in England since 1823; and yet it is only rarely cultivated as a conservatory plant, notwithstanding its great beauty and delicious fragrance. Probably it finds much more general favor in American gardens than it does here. I have seen small plants of it grown in six-inch pots, the branches not more than eighteen inches long, and perhaps three or four of them each bearing large corymbs of flowers. A few years ago a large quantity of seeds of *L. gratissima* was received from India and was distributed liberally, yet the plant remains scarce here. Cuttings do not strike root easily, but a stock of plants may be raised from layers. If the branches of a flowering specimen are layered they are certain to flower the year following, if properly treated. In an ordinary greenhouse here this *Luculia* would not flower, although it grew freely, but on being removed into a warm, sunny greenhouse it has, after a year's growth, flowered most profusely. *L. gratissima* is a native of temperate Himalaya, from Bhotan to Nepal, where it forms a spreading Cinchona-like shrub, twelve to sixteen feet in height. The leaves are lanceolate, about six inches long; the corymbs are terminal, often six or eight inches through, crowded with long-tubed pale pink fleshy flowers, the lobes spreading out flat and forming a limb one and a half inches across. They expand in December and last a month or more. *L. Pinceana* differs from the above in having thicker, more closely nerved leaves, and a pair of tubercles at the base of each corolla-lobe. It is a native of the Khasia Mountains.

CATLEYA REX.—This plant was described in the *Gardeners' Chronicle* a year ago by Mr. J. O'Brien, who had seen it in the establishment of L'Horticulture Internationale at Brussels. A picture of the flowers was published in Part I. of *Lindenia* (English edition) last February, and the plant was described as having been "originally discovered by Monsieur J. Linden during his travels in South America, and again thirty years later by Wallis, who proclaimed it the most beautiful of Cattleyas." Living plants of it did not, however, reach Europe until last year, when it appeared in the collection of the above company, flowering in December. This species is said to be like *C. maxima* in the number of flowers produced on each raceme, and also in the length of the pseudo-bulbs. The flowers are as large as those of *C. aurea*, and are not unlike the white form of that species known as *C. Imschootiana*. Six flowers are represented on a raceme in the picture published in *Lindenia*, and I have been informed that old inflorescences show the scars of twice that number. Such a character ought to be sufficient to remove this plant from the *C. labiata* section of the genus although it was placed in that section by Mr. O'Brien. A few months ago several plants of *C. Rex* were disposed of in England by auction sale, and realized exceptionally high prices. Messrs. Linden now advertise an auction sale of 150 plants of this *Cattleya* in the rooms of Messrs. Prothero & Morris, on January the 8th next. The advertisement is sufficiently interesting to be quoted. It is as follows: "*Cattleya Rex*. The most famous Orchid ever introduced. Good imported plants, five, ten and twenty guineas each, according to size. The whole of the rest of the importation to be sold by auction on January 8th. Monsieur Ellner, our intrepid collector,

who has been searching for it for two years, writes that 'it is impossible to find any more.'"

CYMBIDIUM CYPERIFOLIUM.—I recently saw this in flower at St. Albans, and plants of it have this week been offered for sale at the auction rooms. It is not unlike *C. giganteum* or *C. Lowianum* in habit, but the leaves are shorter, narrower and more elegant, and the flower-bracts are larger. The scape is shorter than the leaves, semi-erect, bearing from four to seven flowers; sepals and petals linear lanceolate, acute, pale green and yellow, streaked with red-brown; lip narrow, pubescent within, white with red spots. The size of the flowers is almost that of *C. giganteum*. The plant is decidedly ornamental. It appears to thrive under the same treatment as answers for *C. Lowianum*. It is a native of the sub-tropical Himalayas. So far as I can ascertain, it had never been in cultivation until Messrs. Sander & Co. introduced it this year.

CYPERORCHIS MASTERSII.—A plant of this somewhat rare Orchid is now in flower in the cool house at Kew. It has erect, narrow bright green strap-shaped leaves, eighteen inches long, and almost horizontal scapes a foot long, decurved and bearing six flowers two inches long, white, with a few spots of red on the labellum and scented like Almonds. The general form of the flower is that of *Cymbidium eburneum*, but smaller. *C. Mastersii* was introduced many years ago from Assam. Lindley figured and described it in his *Botanical Register*, 1845 (t. 50), as a *Cymbidium*, a name by which it is still best known in gardens. It enjoys the same treatment as suits *Cymbidium eburneum*. A few weeks ago a second species of *Cyperorchis*—namely, *C. elegans*—was in flower in the same house at Kew. It differs from *C. Mastersii* in having a drooping, many-flowered raceme, and flowers of a pale straw color. Both this and the above remain in bloom a month or more. The only other known species of *Cyperorchis* is named *C. cochleare*. This has brownish green sepals and petals, and a yellow lip spotted with red. I have never seen living plants of it. It will be seen that the genus is made up of three species previously known as *Cymbidiums*. Sir Joseph Hooker states in his *Flora of British India* that, "except by the narrow lip, long hypochile, and small usually orbicular epichile (or midlobe), it is not easy to separate this genus from *Cymbidium* . . . and *Cyperorchis Mastersii* resembles very much *Cymbidium eburneum*."

CHRYSANTHEMUMS.—a correction. Through a slip of the pen I stated in the letter published on December 2d that five hundred new varieties of *Chrysanthemums* were submitted for certificates to the National *Chrysanthemum Society* at their exhibition held in November. The number ought to have been stated at fifty.

A Remodeled Plant-house.

SOME of my professional friends have been curious to know how I managed a greenhouse without any attention during the long day. From their point of view, with an eye to a sure crop, the inevitable changes of temperature seem fatal to success. Yet the thing is easily done, especially with a small house, and I do not find that moderate variations have any serious effect on the growth of my plants or their flowering. Of course, night temperature is important, and is more under control. By keeping the ventilators open, more or less according as the air outside is still or blustering, and by keeping a fair fire going, the plants have a plentiful supply of fresh air and are not chilled, even should there be a sudden drop of the thermometer. Some time since I described in *GARDEN AND FOREST* (vol. iv., pp. 55 and 67) the small, cheaply constructed house which has answered my moderate requirements, and has been a source of much pleasure at very little cost and care. At first there was trouble with the ventilation; the cold air from the top of the house stiffened the muscles of my back as I worked at the benches, and could scarcely have been good for the plants. However, I quickly turned the current of air by putting in a bellows-ventilator in the end of the house. This was done by making an opening two and a half feet long

Fig. 3.—Pinus Monticola on the Californian Sierras.—See page 4.

and a foot wide, to which a board was hinged. Cotton cloth was nailed to the edges of this and the greenhouse-wall, so that by opening out the board the air is conducted over the pipes and heated some before flowing into the house. A hood at the edge of the bench in front of the ventilator confines the air somewhat, and prevents it from passing out before lingering over the pipes. By opening the ventilator at the end sufficiently, downward draughts from the top of the house are entirely obviated.

Alongside of my house I have had a six-light cold frame, which has for a long time been a great care and annoyance. Cold frames are indispensable in a garden for storage, and are much used, of course, for growing plants. While I have used them for that purpose, it has always been under protest, for shifting sashes and covering and uncovering in all weather are labors not to my taste. There are some garden operations at which I draw the line. There is seldom a difficulty without a solution, and at last the six-light sash has gone, and I am enjoying the satisfaction of cultivating my half-hardy cold-frame plants in comfortable quarters. This was managed by a very simple re-arrangement, making what is practically a cold annex to my greenhouse. As this annex is proving a success, perhaps a few details may give useful hints to some fellow-amateur fond of hardy plants. The original house, it may be remembered, was a span roof eight feet wide, and with three-foot walls. The first operation was to set up four posts twenty inches outside of the wall, and on top of these a girder four inches by three was secured. Then the sashes on one side of the house were lifted and lapped on the girder, putting in new rafters, of course, to hold them. Outside of the old frame a new frame was made two feet wide of boards nailed together, with tarred paper between, and sunk in the earth nearly to the level of the surface. On top of these was spiked a two by three plate-piece, to which were fastened sashes one foot wide and three feet long. On top of these is another plate piece chamfered on one edge, to which was nailed a drip-board. Sashes are hinged on the girder, extending to this board. The ends were glazed, which completed the enclosure of the house. Inside entrance is gained through the furnace-room, and the path being sunk to the level of the furnace-pit, nearly two feet below the main house, there is six feet head-room over this. The space under the new sash is now a solid bed of earth six feet wide.

Fig. 3.—End-section of Plant-house, the addition in dotted lines.—See page 6.
A. Solid bed. B. Paths. C. Proposed fernery. D. Hinged sash.

In planning the changes my theory was that the warm air rising on both sides of the benches should keep the plants on them comfortable, and that in cold weather, when the ventilators are mostly closed, the cooling air would flow into the annex and temper it. The space above the wall was left open for this purpose, the opening being fourteen feet long and two feet wide. The arrangement has proved satisfactory, and there is usually a difference of fifteen to twenty degrees in night temperature between the two sections. The revised cold frame now appears as a solid bed, six feet by eighteen, at which one can work comfortably in any weather, and the temperature can be kept as low as may be desired. The sashes being hinged, by putting in partitions it is possible to make such variations of temperature as may be desired for different collections of plants. It will probably be several seasons before I shall work out the possibilities of my new acquisition, but this season I have flowered there a good crop of late Chrysanthemums, and have it now planted out with a few Roses, Carnations and Pansies, and a large collection of bulbs, Primulas and small hardy plants in pots. Azaleas and Genistas are seemingly destined to do well. It seems a capital place to bring on bulbs slowly.

There is one other change which I have postponed to another season. By dividing and removing half of the wall of the warm section, taking out the earth under the bench and putting in a stone wall at the edge of the inner path, there will be room for a temperate fernery two and a half by fifteen feet. Of course, it will be necessary to board this over to confine the heat to its present course. In this fernery there will be head-room of two feet at the rear and three feet at the front. There does not seem any reason why temperate Ferns and some other plants growing under the same conditions should not do well there. Of course, the wall will receive attention, and being laid up with earth will be planted with suitable Ferns, Lichens, etc. To resume, I have apparently improved my main house by getting more head-room and a less stuffy inclination of air, have gotten rid of a care in the cold frame, exchanging it for an equally suitable place for the plants—in some cases a more suitable one. My current work is scarcely increased, as the cool section dries out very slowly and seldom requires watering. The care of the stove, of course, is no greater. It will be seen that when the alterations are complete there will be in all two three-foot benches, a two-and-a-half-foot fernery, and a six-foot bed in a width of fifteen feet of greenhouse, which seems a fairly economical utilization of space. The tank sunk in the end of the path, I fear, will prove too cool to be of much service. As a measure of precaution, I have provided a covering which can be rolled over the lower sash should there occur very extremely cold weather, for, while the furnace has a capacity sufficient for both houses, I prefer the protection to the hard firing, which would possibly give too much warmth in the warm section.

Elizabeth, N. J.

J. N. Gerard.

Cultivation of the Hellebores.

THESE plants are easy to manage. They prefer a light rich soil, and a position comparatively dry and sunny in winter, and cool and shaded in summer. Shade at any season of the year is not an absolute necessity, full exposure to the sun being rather beneficial than otherwise, provided the roots can be kept moist and cool in hot weather by frequent and thorough watering. Most of the Hellebores grow naturally in soil of rather poor quality, but they make better foliage and flower more profusely under liberal garden treatment. A good method to pursue in planting is to excavate the soil to a depth of about two feet, replacing it with a mixture of fresh loam, leaf-mold and thoroughly decomposed farm-yard manure in equal parts, the best compost for all kinds of Hellebores, whether grown in the garden or in pots. The work should be done in early spring just as the new growth makes its appearance. It is unwise, however, to interfere with the plants when they are established and doing well. Sometimes they require fresh soil, or it is desirable to increase the stock, and then removal is necessary. A surface-dressing of rich manure will generally be found sufficient to keep old plantations in good condition if the soil about the roots is well drained, so that it does not become sour by stagnant water.

The manure should be applied soon after the flowering season, and allowed to remain on the soil all through the summer, and until a covering is again required in spring, when the exhausted remnants may be raked off. This mulch is very beneficial to the plants, apart from the nourishment they derive from it. The litter of the manure protects the roots against drought, and when no enrichment is needed a mulch of similar kind should be used. The lack of moisture at the roots is the great obstacle to overcome in cultivating these plants.

The flowers appear at a time when they are most valuable, on account of the dearth of other hardy flowers; but, unfortunately, their beauty is easily tarnished by the storms which then prevail. The only way to meet this difficulty is to arrange the plants compactly, so that a frame may be placed over them. Many object to such a contrivance as unsightly; but unless one has a cold greenhouse, in which the plants may be grown, the frame is the only cheap and handy way of securing perfect flowers and foliage in their proper season. And, after all, the flowers, lasting as they do from eight to ten days in water, are most enjoyable when cut in a perfectly clean condition and used for indoor decoration.

Much has been written about the inadaptability of Hellebores for forcing. They are not good subjects for this work. By exercising care, however, much satisfaction may be had from them. It is sometimes thought that they may be taken from the garden, potted and placed in heat immediately as successfully as some other hardy plants. Nothing can be farther from the truth. There are few cultivated plants to which artificial heat, applied without judgment, is so deadly.

The heat must be applied very gradually. The plants to be forced, moreover, should be grown in pots, plunged in the ground during the growing season, and not torn from the soil when they begin to show flower-buds. Grown outdoors in pots, they should be taken up early in autumn and again plunged in the earth of the frame or greenhouse where in time they are to have artificial warmth. The object of this second plunging is to maintain coolness and moisture about the roots until the flowers are developed. Plants under glass should always have an abundant supply of air, especially when under heat, and at no time should they be allowed to lack water. Not infrequently good forced specimens are killed completely by transferring them directly to the garden again. Hardening-off demands as much patience and judgment as inuring the plants to a high temperature, and without this the chance of retaining the stock for another year is very remote.

The species and varieties may be multiplied by dividing the roots in spring, when the plants are starting into growth. Select only strong portions for this purpose, and plant them in a rich soil. The pieces that have an unhealthy look always make sickly plants, when they grow at all. The plump, clean portions, no matter how small, grow vigorously and form good plants in a single season. Seeds can be used for propagation, but this is a tedious and uncertain proceeding. The seeds should be sown in a well-prepared cold frame, removing the plants to the open garden when large enough, which is generally from a year to eighteen months after sowing. The seedlings make slow progress at first, and they seldom flower before they are three years old. New varieties are not easily obtained in any other way, and it is the only resource of hybridizers; but, for all other purposes, propagation by division is by far the better method. It should be remembered, too, that a large proportion of the seedlings raised are quite unworthy of perpetuation as garden-plants.

M. Barker.

Auriculas.

PRIMULA AURICULA is known as the Alpine Auricula to distinguish it from the fancy or exhibition kinds which have originated from the same source, but are the result of many years of careful cultivation and selection. Of the fancy Auriculas we have no need to speak here further than to say that they are not in commerce in this country, and probably never will be, as their constitution is much less vigorous than that of the parent *P. Auricula*, and, as a result of a generation or two of coddling, they are less hardy and much more liable to insect pests than the original stock. Fortunately for us the species has been preserved, and we still can cultivate it and enjoy its distinct beauty and fragrance. The best way to secure a stock of Auriculas is to get seed of a good strain, for there are marked differences in the quality of the flowers and the germinating power of the seed. The best time to sow the seed is the present month, for, as the seedlings are of rather slow growth in their earlier stages, it is much better to get them up to a good size before the heat of summer is upon us. Weak plants melt away under a hot sun, and the efforts of a whole season are lost.

If seed be sown now the plants will be large enough to pot off in March, and by May or June they can be planted out in a frame, where they can be shaded in the hottest part of the day, as heat is much more trying to them than cold. If the young plants have partial shade they will grow more or less all summer, and in fall will make rapid progress during the cool nights, and by the time winter sets in they should be thoroughly hardened off to withstand the cold. They will become hardened naturally, unless kept covered with sashes when there is no necessity for them, and when cold weather sets in a few dry leaves or Pine-needles may be spread among the plants, and shutters may be put over until spring, when the plants will start to grow, and flower as soon as the covering is removed. The plants are not hard to suit in the matter of soil. Loam, with leaf-mold and a little fertilizer, will be found satisfactory. Auriculas are fond of moisture, and during the growing season must have plenty of water, hence the difficulty of growing them in pots. When the foliage is large and thick the pots are covered and water difficult to apply, so we prefer to plant them out in frames, from which they may be lifted and potted in the flowering season, if wanted for indoor decoration, for which they are well adapted, as they last well and have exquisite color and a pleasing fragrance.

The only real difficulties in the culture of these Auriculas are the heat of summer, for which shade is an easy remedy, and the freezing and thawing of the winter season. If kept dry overhead frost does not injure them, but frost and wet

combined often rots them, hence the need of covering and a space for the circulation of air, when the plants will winter well and flower the spring after they are sown.

Those who have only the convenience of a cold frame will find great pleasure in cultivating Auriculas, as there are almost always some in flower where plants are grown in any quantity. Unfortunately, few attempt to grow them. I can sympathize with those who are discouraged, for some of the seed I used last spring proved disappointing. It is a great point gained if the seeds are authentic. We are told by dealers that Auricula-seed has a trick of waiting a year, or oftener two years, before it germinates, but I find that if the seed is good, all that has not given plants ready to prick off at the end of three months is not worth waiting for any longer.

E. O. Orpet.

The Thrifts.

AS a class of free-blooming perennials of neat habit the Thrifts, or Armerias, are possessed of much merit. All are tufted in growth, forming dense, hemispherical masses of evergreen foliage, while the flowers are borne in round heads on clean, long, wiry stems. Their season of blooming extends over most of the summer and early autumn, and in several of the varieties it is almost continuous throughout the growing season. Used in groups in mixed borders, in rockeries or as edging plants, they are clean, and give a variety of foliage and flower. Soil is a matter of small importance to them, provided it is not excessively wet.

A. vulgaris, the most common form, makes broad, slowly spreading tufts of dark green, linear foliage, and bears its purplish lilac flowers in loose heads on stems averaging six inches high. The variety *Alba* is very desirable, with lighter-colored foliage and pure white flowers in more compact heads. The variety *Lauchiana* is its best-colored form, with clear, deep crimson flowers, and is a very constant bloomer when seen in masses. Some time since Herr Max Leichtlin, of Baden Baden, sent out seed of *A. undulata*, and it has proved an acquisition, with unusually long, narrow, undulated foliage, and bears pure white flowers in nodding heads on bending stems ten to twelve inches long. It is an almost continuous bloomer with me and very hardy. *A. plantaginea*, with its broader foliage in dense rosettes, produces larger heads of pale rose or lilac flowers, often fading to white on stems often eighteen inches long. The variety *Formosa* is decidedly good, with showy, clear, deep pink flowers in large heads, and with us in a bed of fifty plants is never out of bloom from early June to killing frosts. Its long-stemmed habit and continuous blooming quality renders it especially valuable as a cut-flower. *A. cephalotes*, though the largest-flowered species, with us does not seem worthy of recommendation, owing to its objectionable habit of dying out the second or third year.

Reading, Mass.

J. Woodward Manning.

The Whorl-flower, *Morina longifolia*, has proved hardy with me in a variety of soils and exposures for the last three years. It is a plant of Indian origin, being a native of the Himalayas in Nepal at high elevations, and its flowers and foliage are striking. The leaves are narrow, about a foot long, deep, shining green in color, deeply cleft with wavy, margined lobes, thickly set with thistle-like spines, rendering careful handling a necessity. The flowers are tubular, with a broad, open mouth. In the bud and early stages of opening they are white, but soon change to rose and finally deep carmine in the throat, lightening in color to pale pink or white on the outside. They are borne in clusters or whorls at the base of the stiff, spiny upper leaves, together forming a leafy and floriferous long spike. The peculiar and unique change in color in flowers and the showy, thistle-like foliage, together with the glistening color of the latter, combine to render the plant fit for any collection and worthy of association among the best of hardy perennials. Until entirely proved for hardiness in moist or stiff soils, it would be well to give slight protection the first winter.

Correspondence.

In the Shore Towns of Massachusetts.—V.

To the Editor of GARDEN AND FOREST:

Sir,—Orleans is a town of beautiful landscapes and attractive building-sites, and the summer people are beginning to appropriate them. A wise foresight would provide a large area here for out-of-door rest and recreation, a pleasant reach of shore-land, where thousands of inland people might bathe

and walk by the sea, but there is no park or common or public beach. The time is coming, as in other shore regions, when there will be throngs of people all summer long—the autumn is the best of the year on the Cape—and when there will not be much more space or freedom for them than convicts enjoy in the state prison, marching in lock-step to dinner and away from it again. The summer dwellers here will have their rooms in the cottages and in great hotels and boarding-houses, and they will have the freedom of the sidewalk and the public road. There will be no rambling over breezy uplands, or musing where the rolling surf beats and thunders on the shore. The uplands will be an almost continuous village, and the shore everywhere will be in somebody's backyard. Those who wish to see the Cape country before its wildness and freedom are displaced by the new stage of civilization, with its warnings "Private grounds" and "Keep off the grass," forbidding visitors to leave the highways, should visit it within the next few years.

Orleans can advertise one attraction which I suppose not many towns can rival. The alms-house is not needed for its original purpose, for long and long it has had no pauper tenants, and has been constantly let for a dwelling. Think of living in a town where even the poor-house brings in an annual revenue! Who says the Cape is a barren region and poor? There are many inland ponds or lakes here, some salt, many fresh. If they had been made expressly for purposes of pleasure and recreation they could not have been better. The Orleans Cemetery Association owns the new part of the cemetery. It is on a hill, with a fine view of the ocean and bay, and the summer people go there in numbers. The old part is not so high. The title to it is probably in the town. There are three wind-mills in Orleans, each about 150 years old. A man from the city with a new place here thought he would buy one of these mills and set it up in his grounds as an article of "bigotry and virtue," but the owner of the mill asked \$300 for it. The summer resident concluded that he would try to get along without a wind-mill, and the "boom" in these antiquities came suddenly to an end. The town clerk bought one-fourth of the one at Orleans village for \$25, and it pays for itself by its tolls every year. These mills are about thirty or thirty-five feet high, and twenty feet in diameter at the base, which is square or octagonal. They are not picturesque objects, though it is the fashion to say they are. They are too small, and all their lines too severely simple to be impressive, and they are interesting only because they are unfamiliar to most visitors. There is a valuable public library here, and the town owns a very small area around the library building. The town-hall lot should be considerably extended while land is cheap. It is far too small for permanent public convenience. Hon. John Kenrick, A. T. Newcomb, David L. Young and George S. Nickerson are much interested in the objects of the Trustees of Public Reservations, and will aid them in any convenient way. There was a meeting here early in December to consider the need of open spaces for public resort. After experimenting with the topic at meetings in Boston and at Provincetown I found here that an average country audience responds readily to a direct presentation of the essential facts and obvious deductions related to this matter. It is always interesting to try the effect of a new subject on audiences of different kinds.

Eastham has no considerable public holdings. The early history of the town is interesting, but it receives little popular attention. I noted that in 1705 the town voted to fine any freeman living within seven miles of the polls if he failed to attend an election. Some interesting experiments in Asparagus-culture made here during the last few years give promise of a new and highly profitable industry for farmers and market-gardeners, and Turnips grown in this region are said to distance all competition. Under existing local conditions such facts are of great interest and importance. Wellfleet is an attractive town. All its interests are at present much depressed by the decay of the old industries of its people—fishing, whaling and boat-building. Much land has been bought here by non-residents within a few years, but not much of it has been occupied or improved. The town formerly owned Great Island and Beach Hill, but sold these holdings a few years ago to Mrs. France B. Hiller, of Wilmington, Massachusetts, who also bought much land of private owners in the town. I believe she is to expend a specified sum within a certain term of years in improving the lands bought from the town, otherwise the title will revert, and the property become again a public possession. No improvement has yet been made. People in the town say that many persons made claims for compensation for their rights in one of the private estates bought by Mrs. Hiller, and that "she bought them out, a thousand of them, for a dol-

lar apiece. Whoever wanted a dollar said he was one of the heirs, and she paid him a dollar, and he signed away his right, whatever it was." Perhaps this is the beginning of the growth of a legend. The town long ago planted a considerable tract on Great Island with Pines, and they have grown well. It owns a small piece of woodland—no one knows its area—which supplies all the fuel needed for the schools of the town, and will do so for many years to come, though the timber does not grow as fast as it is cut. It is but a few acres in extent, and is said to have belonged to the last survivors of an Indian tribe, and to have reverted to the town at their death. Wellfleet recently bought a playground near the High School building at a cost of \$150. The area is 280 by 286 feet. There is an old cemetery on Taylor's Hill, owned by the town. Its dimensions are 171 by 144, 149 and 167 feet. Beach grass, no trees. The hill is seventy or eighty feet high. No interments for many years. A land company is operating at South Wellfleet, and has sold hundreds of lots. Wellfleet had once 160 sail of sea-going vessels, now not over twenty. The valuation of property for taxation is declining. A profitable beginning at garden-farming has been made here and in the next town, Truro, and there is room for a great extension of this industry in both towns. There are some historic places in Truro which should be marked, and the early history of the town is worthy of far more attention than it receives from the present inhabitants. Popular interest in the local history will probably have a new development, as Mr. Shebna Rich, of Salem, has written an interesting and valuable history of Truro. Several small tracts of land have reverted to the town by non-payment of taxes. None of them is suitable for a reservation for public resort. All visitors here go to Highland Light. I refer my readers to the accurate and entrancing description of the excursion in Mr. Frank Bolles' new book, "The Land of the Lingerer Snow." All this shore should be forever accessible to the public. (My report on Provincetown was published in GARDEN AND FOREST for October 21st.)

I have just reread Thoreau's book on Cape Cod. It is interesting but one-sided, as it was meant to be. The author walked along the shore, keeping to the very edge of the water nearly all the way down the Cape. He did not see the country inland, and appears to have had an entirely erroneous idea of it. He says himself, "Our story is true as far as it goes. We did not care to see those features of the Cape in which it is inferior or merely equal to the mainland, but only those in which it is peculiar or superior. We cannot say how its towns look in front to one who goes to meet them; we went to see the ocean behind them. They were merely the raft on which we stood, and we took notice of the barnacles which adhered to it, and some carvings upon it." The Cape region is much better wooded, has better soil, and is far more interesting and attractive than his account of what he saw along the beach has led people to believe. His book is usually read as if it were an adequate description of the Cape country; but all his readers should make large allowance for Thoreau's love of paradox, even when he has seen what he describes. I suppose that what he says of the few people whom he saw during this excursion is strictly true, but it does not apply to the Cape people in general any more than to the people of the author's own town of Concord; or, to give a better idea of it, it is exactly of a piece with his description of Boston: "I see a great many barrels and fig-drums, piles of wood for umbrella-sticks, blocks of granite and ice, great heaps of goods, and the means of packing and conveying them, much wrapping-paper and twine, many crates and hogsheads and trucks, and that is Boston. The more barrels, the more Boston. The museums and scientific societies and libraries are accidental. They gather around the sands to save carting. The wharf-rats and custom-house officers and broken-down poets, seeking a fortune amid the barrels, their better or worse lyceums and preachings and doctorings, these, too, are accidental."

The wonderful "Cape Country," with its indefinable charm, seems to me the most interesting region in New England, or anywhere. There ought to be a new book about it. It has no such place in our literature as it deserves. As I walked through it, the extraordinary purity of the air made me feel that I should like to be a gypsy and camp out in all the towns. After we pass Chatham, going down the Cape, the atmosphere is the same as if we were on a small island far out at sea. Every possible breeze is a sea-breeze, no matter from what quarter it blows. I once camped out for a while in the snow on the mountains in the Crater Lake region, in sight of Mount Shasta, and that is the only time I have ever tasted elsewhere an atmosphere so vivifying as that of the Cape Cod country. The number of ponds and lakes on the Cape is much greater than most people know, and the inland scenery is serene and

restful, but not dull or tame. For people who want sea-air our country has no better region, and in a few years it will be thronged and crowded by summer dwellers, from Provincetown to the shores of Buzzard's Bay. It will be a paradise for women and children while the wildness and freedom remain unspoiled. Unless great areas here are made public holdings, free for the people's enjoyment forever, the time will come when the tired dwellers in the cities, and in the vast interior of our country, who are driven by the heat of summer to seek rest and new life by the sea, will find here the city over again, and be "cribbed, cabined and confined" in conditions very like those from which they are trying to escape. That would be a sad sight for thoughtful men.

Franklin Falls, N. H.

J. B. Harrison.

Rare Varieties of Apples.

To the Editor of GARDEN AND FOREST :

Sir,—In regard to the difficulties attending the attempt of N. D. to obtain other than the ordinary varieties of Apples, I would say that nurserymen must be largely governed by the law of supply and demand, and nursery stock, unlike many other articles of trade, soon deteriorates in quality and salability by keeping. Planters of orchards for commercial purposes, whose sole object is profit, confine their planting to few varieties, and those well-tested sorts that promise to serve their purpose. Novices and experimenters, who seek only their family supply, indulge in a larger range of varieties, but they naturally find that the leading sorts receive most attention from nurserymen. It requires a good deal of boom to dispose of much stock of any new thing, and generally at a much higher price on account of this increased expense. The very limited call for some old and once valuable sorts makes it unprofitable to grow them, and even a few trees would exceed the demand till they outgrew a salable size. I am a little surprised, however, that Cogswell and Baily Sweet, and even the Winesap, proved hard to find. These are all old and good kinds, and ought to be on sale in limited quantities in some of the eastern nurseries. Stephen Hoyt's Sons, of New Canaan, Connecticut, ought to have them, especially the first, as it is a Connecticut fruit. Arkansas Black is a western Apple, and probably has not made any reputation east as yet. Stark Brothers, of Louisiana, Missouri, propagate it largely. Winesap could doubtless be had of them in any quantity desired. William J. Heikes, of Huntsville, Alabama, could also probably supply them. These firms make more of a specialty of new fruits than some of our eastern growers. Princess Louise is a new Apple of Canadian origin, and probably has not yet acquired American citizenship. L. Wolverton, of Grimsby, Ontario, could probably furnish your correspondent with trees or cions.

The only mention of Palouse I have seen was in the *Rural New Yorker*, where this Apple is said to have originated in Washington from Illinois seed, and it is doubtless too young yet to have attracted much notice east.

My advice to N. D., if he fails to secure what he wants after reasonable effort, would be to take good thrifty trees, irrespective of variety, preferably of one kind if straight and of vigorous growth, so as to make a uniform foundation for my orchard. After setting them I would secure grafts of the varieties I wanted from those who have fruiting trees. Get a few grafts and bud or graft the young trees with them. There are in many sections of our country excellent old varieties that are well worth growing in localities suited to them that can be had in no other way, as they are not known and recognized in general pomological society. Many such will be lost unless some appreciative friend saves them in this way. The process is simple and the expense is light. The mail could deliver a few cions of Palouse from Washington at one-tenth the cost of a tree, probably one-fiftieth, and with more safety.

Montclair, N. J.

E. Williams.

To the Editor of GARDEN AND FOREST :

Sir,—In reply to the inquiries of your correspondent, N. D., in a recent issue, let me say that the Arkansas Black Apple can be procured from Mr. W. G. Vincenheller, Springdale, Arkansas. Many of the other western nurserymen are propagating it. I think all of the other Apples mentioned by your correspondent can be procured from nearly any of the large western nurseries except Princess Louise and Palouse. The latter I have carefully tested, as far as the fruit is concerned, and find it to be a very good apple. It is medium of size and beautifully colored, red striped and yellow. The quality is very good, and I think it will keep quite well through the winter.

Department of Agriculture, Washington.

H. E. Van Deman.

Meetings of Societies.

American Forestry Association.

THE tenth annual meeting of this society, held in Washington last week, was more interesting and encouraging than any which has preceded it.

On the forenoon of the first day of the meeting the report of the Executive Committee was read, showing that the special effort of the year has been to secure Reservations of public timber-lands under the Act of Congress of March last, which authorizes the President, "by public proclamation, to declare the establishment of such reservations and the limits thereof." Encouraged by this law, the Association has gathered and laid before the President facts and arguments to induce him to make certain reservations. The recommendations have been favorably received by the President, the Secretary of the Interior and the Commissioner of the General Land Office. Surveyors from the Land Office have been sent to examine the tracts. Several reservations have been made already, while others are under examination.

A meeting for discussing this subject was held on Tuesday afternoon, when the Executive Committee presented the following declarations :

"1. Reservations in detached localities, while perhaps preferable to none, will not satisfy the needs of forest-protection unless their number is sufficiently large to embrace practically all the remaining public woodlands.

"2. The all-important problem is that of the management of these reservations, made or to be made, which should be solved at once and simultaneously with the making of the reservations.

"3. The principles upon which such management must proceed are laid down in a draft of suggestions for a bill, in which are provided safeguards to protect prior rights ; return of agricultural lands to entry ; licenses to prospect for minerals, to camp, fish, hunt and otherwise use the reservations legitimately ; licenses to cut timber under regulations adapted to the necessities of the locality ; protection against fire and theft, and such organization as will secure, with the co-operation of state authorities, the objects of the reservations, and at the same time offer as little friction as possible to existing conditions."

Secretary Noble was present, and declared himself heartily in sympathy with the aims and purposes of the Association. He invited the Association to present to him its recommendations, and promised to do all in his power to further its desires.

The Commissioner of the Land Office was prevented from attending by sickness in his family, but a paper from him was read by Mr. Jecko, an agent of the office, expressive of his sympathy with the purposes of the Association. Senator Dawes, in speaking of the inroads made on the forests by invaders, said that the ingenuity of the law-maker has not yet equaled that of the spoliator. He believed the sentiment of Congress and the country was to preserve the forests and protect them from the invasions of the unscrupulous on all hands. An effort should be made, he thought, to convince Congress of the need of action, and in that body he thought there was an excellent field for missionary work. The active interest manifested by the President, the Secretary of the Interior and the Commissioner of the Land Office was regarded by the Association as a most encouraging fact.

The following is a portion of the memorial presented to the President :

That these reservations are for the good of all is not yet understood by large numbers of worthy but uninformed citizens. This is apparent from the protests made against these reservations. The basis of such protests is that these large areas are to be permanently withdrawn from the use and enjoyment of the people. Such is not our purpose, but the very opposite. The object of such reservations is to increase the sum total of the productiveness of our territory, making each acre do its utmost for the benefit of our people. The lands within these reservations are not fit for agriculture, but are capable under wise management of producing a greatly increased amount of forest-products annually. While it is our wish to permanently reserve the land, it is equally our wish that its products may year by year, under a competent forest-administration, be used by the people under equal and just laws. Especially do we wish to minimize the destruction of forest-areas by fires and the wasteful and erroneous methods of forest-use now prevalent.

If it is once understood that by these reservations neither the bona fide settlement of agricultural lands nor the right of prospecting for and opening of mines is to be interfered with,

and that the demands for wood material are to be satisfied in a legal, equitable and simple manner, while at the same time keeping up supplies by protecting them from fire and waste and by securing their reproduction, it is believed that all bona fide opposition will cease, and the boon, which such reserves promise, will be welcomed by all persons interested in the steady and prosperous development of the western states.

After naming and describing several tracts for reservation, the memorial concludes:

At the same time this Association does not believe that the best results in forest-preservation and management can be attained by partial reservations, but after mature deliberation desires to again record its firm belief that only by the withdrawal of all public timber-land unfit for agriculture, and a complete and independent bureau for its management, can the question of forest-preservation be solved.

The principal papers read were by B. E. Fernow, Chief of the Forestry Division; J. D. W. French, of Massachusetts; Gifford Pinchot, of New York, and President Adams, of Cornell University. We hope to publish extracts from them in future issues. The officers elected for the year were: President, William Alvord, San Francisco, California; Treasurer, H. M. Fisher, M.D., Philadelphia; Recording Secretary, N. H. Egleston, Washington, D. C.; Corresponding Secretary, Edward A. Bowers, Washington, D. C.

Notes.

Mr. R. J. Hinton's *Progress Report on Irrigation in the United States* says that irrigation was practiced by the Indians in Mexico and Arizona at least five centuries ago, and that among ourselves it seems to have been first practiced by the Mormons in their Great Salt Lake settlement.

A correspondent of the *American Florist* commends the new pink Carnation, Grace Battles, as superior even to Grace Wilder, and predicts for it a greater popularity. The flower is said to be larger and a trifle lighter in color. It is borne on a stout stem, and does not burst its calyx. The new plant is one of Mr. Edwin Lonsdale's seedlings.

On very cold nights window-plants are best protected by the homely plan of hanging one or two newspapers between them and the glass. The air between the layers of paper is an admirable non-conductor, and when high winds accompany a low temperature this simple device will often make a difference of ten degrees at the point where the plants stand.

In regard to the danger of sterilizing the soil by applications of the Bordeaux mixture, Professor Halsted writes that he has seedling plants and cuttings growing in soil which contains one per cent. of copper sulphate, and they are as vigorous as similar plants in soil entirely free from copper. It would require a century of spraying on the approved methods before the soil of a vineyard or orchard would contain a like proportion of copper.

A dispatch to *The Tribune* announces that the state fruit-inspectors of California, last week, seized diseased fruit-trees from the east valued at \$5,000. Among these were Peach-trees, with yellows and curculio, and Plums, Prunes and Apricots, also diseased and infested with insects. Eastern nurserymen made vigorous protests, but the inspectors paid no attention to them. The nurserymen do not assert that the trees are free from pests, but they declare that the diseases will not develop in California, a statement which fruit-growers there consider an error.

A prune-grower in Santa Clara County, California, one Gordon, has just refused an offer, it is said, of \$30,000 from a Bordeaux firm that wished to buy his fruit and sell it as the French product. The price offered for the prunes was satisfactory, but the stipulation was made that the prunes should be shipped in sacks. The only inference from this was that the Bordeaux firm would pack them as French prunes. Mr. Gordon would not consent to this, as he believes, if California growers use the same care and skill in packing that the French do, they will soon contest the prune industry with them.

At this season in extensive shrubberies, like many of those in Central Park, beautiful effects are produced by the haze of soft color which hangs over them. This comes from a fusion of the various tints of the bark on the branches. The most casual observers are familiar with the ashen gray of some of the Thorns, the crimson of the Dogwoods and the yellow of

the Willows. But each species and variety of shrub and tree has a color of its own, and as these combine on a bright day every mass of branchlets, at a little distance, is enveloped by a luminous mist, which adds much to the charm of a winter-landscape.

"There is very little forest left in this state," recently said the *Pittsburgh Dispatch*, "which is worth anything for lumber, and meantime the railways are consuming all the hard-wood large enough to make a tie, so that there is no prospect of a renewal of our hard-wood timber in a century, and the Pine and other persistents do not readily reclothe the wastes. But worse than the loss of timber, for which substitutes may be found, is the fact that since the denudation of the forests our climate has become so uncertain that, even with the aid of the Signal Service, no business calculations can be based on the weather, and birds and animals have not yet acquired new instinct such as will enable them to serve us as barometers. Even the hoot-owl misses it as often as the Weather Bureau.

In an address before the Wisconsin State Horticultural Society on plants as affected by cold, Professor Goff stated that whatever we can do in the way of treatment of the soil or of the plant that will induce early maturing of their growth, will tend directly to increase their hardiness. A well-drained soil that warms promptly in spring and retains its warmth late in autumn, and is at all times free from excessive water, is one of the essential requisites to well-matured wood in plants that incline to late growth. Nitrogenous manures tend to stimulate growth, and hence should be avoided, as should cultivation late in summer, since by increasing soil-moisture it tends to a succulent condition of the wood. The growing of some crop that has a large leaf-surface, as Buckwheat, late in the season is of advantage, since it tends to reduce the water-content of the soil, and thus to hasten maturity. Pinching the tips of the growing shoots at the beginning of autumn acts as a check to growth, and thus tends to ripening of the wood. Removing the leaves from young trees that incline to grow too late promotes the same end, and in late varieties of the Apple it is found that a prompt gathering of the fruit has a tendency to promote wood-maturity.

At the meeting of the Peninsula Horticultural Society at Easton, Maryland, the Committee on Small Fruits say in their report that old beds are not the ones that pay the grower, and future years will find them fruiting their Strawberry-beds but once, Raspberries not over four times, and Blackberries not more than seven or eight years. It has been shown that fall or winter plowing is the best for the Strawberry-beds for spring planting, and the old theory that they should never follow a clover-sod has been so completely exploded that we now know that there is no other preparation so good as to turn a young clover-sod one or two years old at the most, and this is equally true for all the berry crops. It has even been found that the mulch for Strawberry-beds may be grown right on the patch, and if the ground is strong and the weeds have been thoroughly kept under, no harm appears to result from ceasing all work on the beds about August 1. The growth of Fall-grass, Crab-grass, etc., which will follow, is all killed by the first heavy frost and, left on the ground, makes an excellent mulch for the berries. Experiments are now going on that promise to harness the Scarlet Clover to the work of improving our berry-patches, as has been done with larger fruits. This may be sown after the fruiting season on Raspberry and Blackberry fields, and a good crop of green manure will be ready to turn under in April, this furnishing nitrogen to the soil and improving its mechanical condition at the same time. It has been shown that potted Strawberry-plants set in August will give a crop of the best fruit the following season, and we believe that as good results may be obtained from layer-plants set out about the time of our early August rains, thus making it possible to grow a good crop of the best berries at a greatly reduced cost for cultivation, and to have a crop of Clover growing during April and May decaying through June and July in the soil that is to grow our Strawberries the following spring.

Ready-made Plans for Planting.

NOT long ago we received the following inquiry: "I have a small lot containing about three-fourths of an acre of land on which I propose to build a modest house. The shape of the plot is nearly rectangular, and it is twice as long as it is broad. Can you refer me to any prepared plan for laying out such a piece of ground which would probably be suitable for my purpose?" It is not to be assumed from this that our correspondent imagines that ready-made plans, in assorted sizes, are kept in stock, and that these can be made to fit any lot of a given size or shape like a ready-made garment, and yet it is plain that he does not clearly understand what kind of problems are to be met and solved in every case where a dwelling-house and its surroundings are successfully adjusted and arranged. We do not know whether this land is in a town or in the open country; whether it is level or on a hill-side. It may be desirable to have a portion of it serve simply as the foreground to some pleasing landscape. Perhaps the planting should be arranged to frame in some distant prospect or to shut out from view some disagreeable object, and we do not even know how the land lies in relation to the points of the compass, not to speak of the direction and position of any outside objects, attractive or repulsive, which must be considered in the design. We know nothing of the size or the character of the house, and nothing of the taste or needs of the family who propose to occupy it, and without knowledge of these and a hundred other essential considerations it is not possible to give advice which will be of real value in any particular case.

We are aware that planting-plans are sometimes furnished by persons who have nothing to guide them but an outline map of the ground. We have known architects to furnish plans for a building before they had ever seen the land on which it was to stand. In a recent instance the plans for a villa of some pretensions were prepared under the impression that the main entrance faced the east, when in reality it looked toward the south-west,

so that every provision which had been made with reference to sunshine and shadow was hopelessly wrong. Few architects, however, would attempt any serious work with so little knowledge of the lay of the land on which it was intended to build; and just here it may again be insisted on that the plan of the grounds should depend largely on the plan of the house, and, for reasons which have often been urged in these columns, the two should be designed together, or, rather, should form one consistent scheme. This means that the approaches, entrances and the various outlooks from the house should feel the influence of their surroundings, which should not only determine where the house should be placed, but how its internal structure should be arranged. It is plain, too, that the planting must, in a large measure, be controlled by the style of the house. Even a detail, like the planting about the house-foundation, should be modified as the building is low or lofty, modest or stately. A varied collection of vines or shrubs of distinct or diverse forms, that would be appropriate along the base-wall of an irregular building, would be out of place along the straight lines of a plainer structure. Convenience and comfort, as well as good taste, demand a perfect correlation between the house and its surroundings.

It is not to be inferred from this that the volumes of plans which have been published are all useless. A complete plan may be most instructive if accompanied by a full explanation of the reasons which guided the artist in each step of his design, and any plan is valuable so far as it can be made to illustrate sound principles. It is true that many published designs are misleading rather than instructive, because the laws they aim to enforce are vicious, and the details insisted on are inartistic and petty; but this is the fault of their authors. They can be made helpful, but no one would ever think of adopting one of them entire for practical use as a working plan. If a plan is good for one place, it is for that very reason unfit for any other, for if it is the best possible for one set of conditions it will be unsuited to another set, and no two places are identical in all their features and relations. Even if it were desirable to reproduce or imitate in the surroundings of one house the effects which have been found pleasing in another, the result would certainly be unsatisfactory. We may repeat without end a fashionable pattern in millinery, but second-hand ideas in gardening are more difficult of adoption. Every shrub or tree has an individual quality, and they refuse to duplicate themselves precisely even in the same soil and exposure, so that it is easier to produce something characteristic and appropriate in any given position than it is to struggle after the reproduction of any landscape-picture, and, in the end, only succeed in making a parody of the original.

After all, the minutiae of planting, especially of such planting as is termed decorative, is a matter of subordinate importance. It is the fundamental design, the way in which the house and grounds and approaches are framed together, and not its ornamental appendages, which determines the essential character of the place. It is the adjustment of these controlling elements which demands special study in every individual example; and although, as has been said, ready-made plans may offer suggestions and exemplify principles, every successful treatment of a house and its surroundings is original and, in a measure, a new creation. It is our belief that the production of such a design is an object worthy of the study of a trained and conscientious artist. Without the thought of a competent designer in a unified plan of dwelling and grounds, the varied wants of a modern household will not be adequately provided for nor its convenience assured. To secure these advantages in full measure is surely worth all the special study which each individual instance can demand, and this is especially true since it is possible, in addition to making the most of every opportunity in the direction of health and comfort, to make the place perennially attractive to the eye of cultivated taste.

WE quote the following paragraph from an editorial article recently published in the *American Architect and Building News*, knowing that other suburban communities, beside those in the neighborhood of Boston, are suffering from the evils therein set forth :

The operations of the Boston Board of Survey, which is authorized by law, on petition of the majority of property-owners in any part of the city, to lay out streets to the territory concerned, establish grades, and construct the streets, assessing the cost on the owners of the land, have attracted the very favorable attention of the inhabitants of the neighboring towns, and Brookline, the richest and most prosperous suburban village, has already voted to petition the Legislature, at its next session, for authority to establish a similar Board of Survey, with the same powers. As the contrast between a systematic, economical and convenient method of laying out streets, and the extravagant, ridiculous, and, in one word, idiotic practice at present in vogue in the other neighboring towns grows more glaring, the example of Brookline will probably be widely followed, and then, at last, will the very important suburban portion of Boston enter upon a period of substantial development. As we once mentioned, out of a total of about one hundred streets in one suburban district, which fairly represents all, more than forty are culs-de-sac, or return to the point from which they started; and every year adds considerably to the number of abortions, while the laying-out of a street which can be passed through, to reach any other point, usually requires the intervention of the County Commissioners, and is an extremely rare event. The consequence is that driving through the Boston suburbs is to a stranger generally one of the most exasperating experiences of his life. Starting, let us say, on a country road, which, however, soon takes a direction away from the point he wishes to reach, he endeavors to find a transverse street which will lead him toward his destination. Of what appear to be transverse streets there is no lack, but to find a navigable one, so to speak, is quite a different matter. Three-fourths of them, in some of the towns, are marked with the warning "Dangerous," and the prudent charioteer takes care not to tempt the perils which lurk within them. Reaching, at last, one without the alarming sign, he turns into it, and drives a few hundred yards, when he reaches a fence, at which the street terminates, either in a neat oval, or a jungle of weeds. Turning, with difficulty, he makes his way back to the high-road, and proceeds, getting always farther from the place he wishes to reach, until he finds another promising-looking street. This, on trial, proves to describe three sides of a square, and conducts him back to the high-road, half a dozen rods beyond where he left it. The next street that looks feasible takes him, between two rows of handsome houses, straight to a pond, and, unless his horse and carriage are adapted for swimming, there is nothing for it but to return to the high-road again. The next public way, perhaps, brings up against a gravel-bank, and another, beautifully macadamized, leads him to a circular park, from which there is no other outlet. By the time he has studied the varied topography of all these specimens of suburban engineering, the day has nearly passed, and he returns to his starting-point with thoughts upon suburban town governments which would hardly bear expression. Of course, the natives understand that the reason why Arlington Avenue comes to a dead stop under a tree is that the owner of the land beyond the tree went back on his promise to extend it through his property; and that Smithdale Street forms three sides of a square because Mr. Smith only had six acres of land, and wanted to have his street all on his own ground; but the knowledge of these personal matters does not do much to console the people who would like to use these avenues for the purpose of getting somewhere, and not as subjects of ethical study; while even the tax-payers, when they find themselves confronted with a heavy appropriation for extending a few of these culs-de-sac to a proper outlet, begin to regret that means could not have been found for having the proper disposition made at the outset. Such a means the citizens of Boston have now provided in their Board of Survey, and, although it has only been constituted a few months, it has shown itself of such immense utility that the general feeling of the citizens is one of deep regret that they have not thought of it before.

Though Nature is constantly beautiful she does not exhibit her highest powers of beauty constantly, for then they would satiate us and pall upon our senses. It is necessary to their appreciation that they should be rarely shown. Her finest touches are things which must be watched for. Her most perfect passages of beauty are the most evanescent.—*Rushin*.

Notes of a Summer Journey in Europe.—IV.

A VISIT to Pallanza naturally includes the far-famed Borromeo Islands, which lie directly opposite. I had only opportunity to visit Isola Bella, a heavy thunder-storm preventing a visit to Isola Madre, which is said to contain some interesting trees. While the terraced gardens of Isola Bella, established two hundred years ago, contain many specimens of interest to an arboriculturist or dendrologist, the whole place is so painfully artificial that one cannot help wishing the fine trees were in some freer, more natural situation. Yet, no doubt, these ten terraces (built on a barren rock, as the guide-books tell us), with their grottoes, fountains, statues and other artificial embellishments, all contributed to complete what in one epoch was considered high-art in gardening. There are many signs of neglect and decadence, and the average visitor is likely to be disappointed in both palace and grounds; indeed, it may be said that the trees and shrubs are the objects best worth a visit to the island, unless it be to get an object-lesson in the taste of past times and to see how thoroughly ugly an artificial garden may be. On approaching the shore one of the most interesting groups noticed is a cluster of some twenty-five or thirty trees of our southern Magnolia (*M. foetida*), which were flowering freely at the time of my visit. These trees are from forty to fifty feet high, and, though crowded together, they were the best group noted anywhere. Among many other specimens, which the gardener points out to every party he conducts, are Cork Oaks (*Q. suber*), three or four feet in diameter of trunk; the tree known as *Cryptomeria elegans*, which here proves quite hardy and very beautiful; a common Laurel, or Sweet Bay-tree (*Laurus nobilis*), whose age is counted by centuries; *Araucaria Brasiliensis*, with a stem a foot and a half through, and also a good representative of *A. Cunninghamii*. Of the genus *Eucalyptus* there are fair-sized trees of several species, some of them being in flower at this time (July 24th). Large Camphor-trees occupy a conspicuous place, and, of course, the Deodar and Cedar of Lebanon are not left out, for without these no such garden would have been considered complete. Some Acacias thrive in the open air here, and so do great Oleanders. *Hovenia dulcis*, which we have not yet been able to grow at the Arboretum, is here almost thirty feet high. As it grows in the Himalayas and Japan, as well as in China, it is possible that somewhat hardier forms may yet be introduced.

Citrus trifoliata is in fruit at fifteen feet in height; an example of one of the Club Palms (*Cordyline [Dracæna] indivisa*) has reached a stature between twenty and twenty-five feet. There are not so many American plants to be seen here as about Pallanza; but among others were noted large bushes of our Candle-berry (*Myrica cerifera*), while a great specimen of the Trumpet Creeper (*Tecoma radicans*) has a stem a foot in diameter near the base. Another *Tecoma*, the handsome flowering Japanese *T. grandiflora*, fifteen years planted here, was just opening (July 24th) its first flowers of the season. A little-known Asiatic climber of the Pea family, *Pueraria Thunbergiana*, is here growing to a great height on one of the walls.

I observed in the vicinity of Pallanza that the Forsythias were bearing a great abundance of fruit. It is perhaps owing to late frosts that these plants, in colder regions, rarely bear many pods or perfect much seed.

After Pallanza, Berlin was the next point where an extended stay was made; but stops were made at Zurich, Munich, Leipzig and the establishment of Dr. G. Dieck, at Zæschen, near Merseburg. The journey by rail over the St. Gothard route does not afford much entertainment from a botanical point of view; but the sail through Lake Lugano, on the way to the St. Gothard line station at Lugano, and the glimpses of mountain and valley one gets from the train, are alone well worth the journey. Lake Lugano is a little gem, surrounded as it is by hills and mountains clad with green from summit to the water's edge, yet within sight of snow-covered peaks. The principal occupations of the district are the cultivation of fruits and the entertainment of foreigners. If natural surroundings, climate, etc., count for anything, it would seem as though a finer race of men and women should be developed here than in less-favored regions.

After passing through the St. Gothard tunnels one sees the mountain-sides marked at frequent intervals by narrow perpendicular scars. These are slides where logs are run down. But with the cutting of timber here there is also some systematic reforestation, especially of Spruce, on the lower slopes. The Fig lives fairly well in the open air in many places about Lake Lucerne, but at Vitznau the plants had been much killed by the severity of the past winter. Few botanical notes were

made until Zurich was reached, and the visit to the Botanic Garden here was made during almost continuous rain. This Botanic Garden is one of several Swiss cantonal establishments of the kind, others being at Geneva, Basle and Berne. It was established about fifty-five years ago, and is one of the very few gardens which make a practice of selling plants and seeds, and it has done so from the beginning. The garden is apparently much frequented by the local inhabitants; but it is not maintained at a high standard, and does not contain much of interest to a foreign visitor. The herbaceous collection is comparatively small and uninteresting; even the Alpine Garden is disappointing, and there are few trees worth special mention. A large tree of *Cryptomeria Japonica* had its tips browned by the severity of the past winter, when the frost was unusually severe, the thermometer registering eighteen degrees below zero (Centigrade) and the lake being frozen over, a rare event.

The Cucumber-tree (*Magnolia acuminata*) thrives as well here and grows as large as it does when planted at Boston, while *Sophora Japonica* is of good size, with a trunk two and a half feet in diameter. This *Sophora* appears to be one of the most commonly distributed of all Japanese trees in European gardens.

One of the most interesting trees in the garden is a specimen of the Clammy Locust (*Robinia viscosa*), labeled under its synonymical name of *R. glutinosa*. This has attained a size not often seen in this species, being perhaps forty-five feet high, while the stem is about fourteen inches in diameter at four feet from the ground. A specimen of the Cephalonian Fir (*Abies Cephalonica*) has a trunk two and a half feet in diameter, while its branches spread twenty feet in each direction.

Lindens, of several species, are largely planted as street trees in Zurich, and the air was fragrant with the odor of the blossoms. One of the shrubs which attracted my particular attention here, and which was also found in several of the squares of Geneva, proved to be *Spiræa Lindleyana*, a Himalayan species too tender to live and thrive well in the climate of eastern Massachusetts, except, perhaps, in the warm southeastern corner of the state. Under some circumstances this species might be mistaken for the common *Spiræa sorbifolia*, of which, indeed, it was once considered a variety. But the common and hardier species is much more dwarf in habit than *S. Lindleyana*, which, at Geneva, was growing in clumps, and ten or twelve feet in height. Moreover, the common species blossoms earlier, and is quite out of flower before Lindley's *Spiræa* begins. The huge panicles of flowers of the latter are usually somewhat flattened or fan-shaped, while in *S. sorbifolia* they are cone-shaped or pyramidal. The leaves, too, are very distinct. *S. Lindleyana* should be a valuable acquisition where the winters are not liable to be any more severe than at Washington.

Arnold Arboretum.

J. G. Jack.

An Evergreen Shrubbery.

I HAVE often wondered why so few broad-leaved evergreens are planted for winter effect. Perhaps the northern climate is too trying for the best of them, but, south of Washington, the list of these plants suitable for cultivation is a large one. Our climate in this section of West Virginia is colder than that of Washington. We have a good deal of ice and snow, and sometimes the Potomac River, which is but a mile away, freezes over, so that one can skate from West Virginia into Maryland. In our grove at Rose Brake we are now testing a number of broad-leaved evergreens, but cannot yet speak in assured terms of their hardiness.

Nothing adds more to the attractiveness of our home grounds at this season than groups of Mahonias, Laurels, evergreen Thorns and similar plants. In this neighborhood the English Laurel flourishes and becomes a large bush or small tree, with charming foliage of a lively green, reflecting the sunlight from its polished surface.

In the Mall, in Washington, thousands of broad-leaved evergreens are planted, including many Aucubas, which seem perfectly hardy there. These I have never tried, as I think them the least pleasing of their class. Their blotched appearance soon wearies the eye, yet if there were only plain green-leaved Aucubas they would be much handsomer and really very valuable shrubs. The yellow variegation is no objection in the eyes of those who admire variegated Altheas, Dogwoods and Weigelas, but my own taste leads me to use this class of shrubs sparingly, for many of them together produce an unnatural effect.

We have tried some interesting experiments at Rose Brake

with plants that are usually considered too delicate to stand the winter in open ground. We leave all Gladioli in their beds with no cover but the leaves which the autumn winds spread over them. One bed, however, which has no large trees in its neighborhood, is left uncovered, and yet the Gladioli live and increase from year to year, and I cannot see that they deteriorate under this rough treatment. *Hydrangea hortensis* has survived several winters with no protection at all. We are now testing *Chimonanthus fragrans*, the Deodar Cedar and *Phillyrea Vilmoriniana*, all duly tucked in with a coverlet of leaves, kept in place with branches of trees. Our small specimen of the great Southern Magnolia has a house made out of a barrel, from the top of which the leaves protrude, green and smiling. Next year I mean to adopt Mr. Massey's suggestion and try the experiment of leaving a *Pittosporum* in the evergreen shrubbery throughout the winter, as he writes that it withstands severe frost in North Carolina.

We have a beautiful Japanese Acacia, *A. Nemu*, now six years old, and it has never winter-killed nor led us to believe that it was not as comfortable in its winter quarters as our hardiest trees. It is about twelve feet in height. Mr. Parsons recommends cutting this Acacia down to the ground every year, but this we find quite unnecessary.

For the evergreen shrubbery the catalogues name varieties of evergreen Thorn, a half a dozen *Andromedas*, *Azalea amœna*, *Berberis dulcis*, many varieties of Box, three or four *Daphnes*, besides *Cotoneasters*, *Ilex opaca*, *Sedums*, the common Inkberry, Furze and two kinds of Irish Heath, *Menziesia polifolia* and its variety *versicolor*, which bears pink flowers. From these a selection can be made for a beautiful shrubbery. Backed by groups of Hemlocks, Pines and Spruces on the north, as a protecting rampart against the cutting winds of winter, such a shrubbery might be a delight to its owner, and rival Addison's favorite evergreen garden, loved by the birds.

The different Boxes seem to me too stiff to be altogether pleasing, but that is a matter of taste. I have some very old Box-trees bordering the paths of my vegetable garden, whose antiquity protects them; but I have set out no young specimens in my shrubberies. Instead, I have hardy Oranges, which I think much prettier. For vines we have the Chinese Honeysuckle and the climbing *Evonymus radicans*. Bitter-sweet is very appropriate to the winter shrubbery, as its berries hang on late in the season, and it forms a pleasant contrast to the heavy foliage of the evergreens. A few Birches are planted here and there among Pines and Spruces for the effect of their white bark, and some rare deciduous shrubs and trees further relieve what might else be the sombre effect of the evergreens alone. *Yuccas* we find very valuable, and have many clumps of several varieties. *Yucca filamentosa*, *Yucca gloriosa*, *Yucca recurva*, *Yucca angustifolia* and *Yucca flaccida* seem unaffected by the snow and ice that surround them, and are a cheerful light green that contrasts well with the darker foliage of our Mahonias, Rhododendrons and Hollies. *Yucca filamentosa* is, however, the only one we have thoroughly tested, as some of the others are now enduring their first winter in open ground.

Evonymus Sieboldii is a choice shrub for winter effect, with its profusely borne orange-red berries and its clean, healthy foliage, and the Scotch Broom, *Cytisus scoparius*, is certainly hardy; and, though it is deciduous, we have given it a place among the evergreens because of the cheerful color of its branches, and its graceful, half-weeping habit. The new variety of this charming plant, which is mentioned in GARDEN AND FOREST, vol. iii., p. 273, as *Cytisus scoparius*, var. *Andreas*, ought to be an acquisition if it were hardy here. It is described as follows: "The bright yellow of the standard and keel of the flowers and the rich velvety maroon of the wings are most effective. It is as easy to cultivate as the type and flowers when only a foot high." Our common Broom flowered when very small, and is a sunny, cheerful plant at all seasons, hardy and brave.

Is it the common English Hornbeam which Addison means when he writes of his garden: "The walls are covered with Ivy instead of vines. The Laurel, the Hornbeam and the Holly, with many other plants of the same nature, grow so thick in it that you cannot imagine a more lively scene"? The English tree as I know it is not very unlike our own blue Beech, a most attractive and small tree. But why is it named in this company?

Following a suggestion in a recent editorial in this journal, we shall plant some scarlet-twigged Dogwoods and *Kerrias* in our winter shrubbery, and to make it complete we should carpet it with Ground Ivy, Winter-berry and Partridge Vine.

All this will come in time. At present we have a great deal of Periwinkle, which we find of an encroaching disposition, but very desirable for planting under the shade of evergreens where grass will not flourish. In some catalogues *Osmanthus illicifolius* is included among hardy evergreens. This, with many others, I hope to report on in future. Meanwhile I am sure that any of your correspondents who have facts as to the established hardiness of any shrubs of this sort which are not generally planted will oblige many readers by giving their experience.

Danske Dandridge.

Winter Rambles in the Pine-barrens.

IN articles in GARDEN AND FOREST of last year some of the characteristics of the Pine-barren flora, as seen at the head of Lake Michigan in the winter, were described. There are additional features, especially in connection with deciduous trees and shrubs, equally attractive to the botanist and observer of wood scenery at this season.

Though a familiar tree throughout the eastern United States, and ranging from the Gulf to our northern limits, the Tupelo, or Pepperidge, as it is better known at the west, is not generally abundant, though frequent in some localities. In the Pine-barrens it is seen in the narrow strips of swampy ground or by the borders of the sloughs, where it grows singly or in small groups. As it is apt to stand apart from trees of a similar height, rising from clumps of Willow and Alder, or other lowland shrubs, its isolation helps to emphasize its singularities, and here it is the most picturesque tree of the lowlands, or even in the landscape as a whole. None of its associates has so marked an individuality or a form so strongly outlined. The crooked and elbowed limbs, mostly sloping downward, give the Pepperidge a more pronounced appearance when leafless, since they are abundantly provided with short stiff twigs nearly as stout as thorns. When the longer branches are near the top, making a flattish crown, it resembles a great parasol. Its striking characteristics lead to its easy identification as far away as the eye can make out its form. The largest of the trees here have a girth of but six or eight feet, and are rarely more than fifty feet high, their trunks often bushy with short adventitious branches below the principal limbs. Thickets of shrub-like trees are common, where the stiff twigs and limbs make them almost as difficult to penetrate as a hedge. It is not always a graceful tree, but when covered with glossy leaves in summer has a rare beauty, and when they assume the crimson hues of autumn it vies with the Sumachs in being the most brilliant object in the autumn woods. Sometimes it assumes a symmetrical and very handsome form, with long lower limbs, and those above gradually shortening to near the top. With limbs so sloping as almost to droop, and coming so near the ground that their ends blend with the low shrubbery beneath, we see a tree when covered with glossy foliage as beautiful as any in the forest.

The Paper Birch, a more common tree and always a graceful one, is found in similar situations, but in poorer soil. It rarely exceeds thirty feet in height, though in some of the more fertile spots, where it shares the ground with the White Pine and Elm, may be double this height. It springs up quickly where the ground has been overrun by fire, making thickets of straight, slender trees. The slim white trunks, frizzled as they grow old with loose bits of papery bark, are in sharp contrast with all about them, striping with bands of white the background of darker shrubs and trees. But when standing alone, or when grouped with others of its kind, the intensity of contrast is toned down, and it presents a most attractive picture. The smooth bark of the limbs, and on the trunks of the young trees, is of a lively chestnut-brown, speckled with small gray dots, also contrasting effectively with that of the white bole and larger limbs. The cylindrical catkins stand out a little stiffly in twos and threes at the ends of the twigs, presenting a fork-like appearance very different from that produced by their long and pendulous habit in spring. Sometimes the tree closely resembles the Cut-leaved Birch, with a light and airy spray, drooping when heavy with leaves and forming a flowing outline. It gives a striking effect of local color when seen in rows bordering some of the long, straight sloughs, which run like avenues of water through the thin woods, and the lines of white, formed by the bright trunks, fade into the distance as the eye follows them down the vista.

Rivaling the Paper Birch in the color-effects of its trunk is the American Aspen (*Populus tremuloides*). It also grows up rapidly in the damper ground of burnt districts, where the smooth, greenish white bark of the slender trees shows conspicuously. The green tinge becomes less marked as the

trees increase in size, and the bark assumes an ashen, or even clay color, but always in strong contrast with the mass of trees around, especially in the winter-time when stripped of leaves.

A near relative of the Birch, the Speckled Alder (*Alnus incana*), is one of the most common of wet-ground shrubs. The smooth stems, with polished, reddish green bark, speckled with gray, show finely in the winter season. The recent shoots are reddish gray, slightly downy, and marked with numbers of small, round yellowish dots. The buds are prominent, of a dark purplish color, and have a shining, waxy coating. Being raised on short, thick stalks, they are somewhat club-shaped. The cylindrical aments are already formed, for it is one of the first shrubs to bloom in spring. They are about an inch long, and hang in clusters of three to six at the ends of the branchlets. Since the bearing shoots curve near the end, the aments almost always point downward, quite in contrast with those of the Birch, standing stiffly outward, and less graceful in this respect than the Alder. They are reddish brown mottled with green, and by their color and position give this shrub features by no means devoid of beauty.

New or Little-known Plants.

Chrysanthemum, Walter Hunnewell.

THIS seedling Chrysanthemum bloomed for the first time in the autumn of 1890. It is the result of a cross between Mrs. J. C. Henzy, a yellow-flowered variety, and Sachem, a bronze. I had a plant of it in a six-inch pot, grown to a single stem, in order to test its bloom, a plan, by the way, which was recommended by Mr. Gerard, in GARDEN AND FOREST, as the best means of testing the flowers of seedlings so as to avoid the necessity of taking up the whole plant. Nevertheless, the seedling's habit of growth was so remarkably distinct that the original plant was lifted, but when it bloomed it did not seem worth keeping, except to use as a parent in future crosses, so that its strong habit could be perpetuated. However, Mr. A. H. Fewkes, of Newton Highlands, persuaded me to give it a trial, and assisted me in the second test. The result was a remarkable improvement on the first year's showing, and Mr. Fewkes secured some superior flowers. Mrs. Henzy, the seed-parent of the new variety, was sent out a few years ago. It has a neat, incurved Japanese flower and a dwarf habit. Its constitution is weak, however, and unsuited to single blooms of a large size, such as are now fashionable, so that it fell out of the ranks and is seldom seen. The pollen-parent, Sachem, was raised by Dr. Wolcott. It bears a semi-double flower, and its only recommendations were a vigorous constitution and an admirable dwarf habit. The flower of Walter Hunnewell (see page 17) is a good orange-yellow, having the finely incurved form of its seed-parent, and the plant shows the distinct and vigorous constitution of Sachem. The flowers are solid enough in texture to keep them from fading, and for pot-culture the variety is an ideal one. It has marked individuality in its good foliage and erect habit, and needs very little staking to keep it in perfect shape. In my experience, also, it produces a greater percentage of crown-buds than any other plant with which I am acquainted.

Iron-clad Roots.

IN a recent issue of *Rural Life*, Professor Budd, of the Iowa Agricultural College, discusses the subject of root-grafting with both long and short cions and roots, and expresses a preference for long cions on long roots. Of course, this kind of graft, planted as the Professor plants them, with only the top bud of the cion above ground, requires deep preparation of the soil, and a good deal of hard digging in taking up the trees. But he believes that the extra cost and trouble are more than recouped by a much better growth and a much smaller number of second-class and unsalable trees. I am inclined to agree with Professor Budd on this point; and just here I venture to give a warning to the growers of iron-clad fruits in the nurseries of New York and other states outside of the "cold north."

A little more than one year ago the propagators of the new winter iron-clad Oldenburgh-seedling—first known as Dudley's Winter, but since renamed North Star—kindly sent me two trees for trial. I had them carefully set out, but one is already dead, and I can save the other only by banking it in the fall. I did not set them myself, nor unpack them, and the man to

probably one reason why "New York trees," even the hardiest Russians, are so widely unpopular in the cold north.

Without the least doubt, so long as we are compelled to work our iron-clad tree-fruits upon tender stocks we must put and keep these stocks well down beneath the surface, or mound them up, or mulch them heavily, and keep them so.

Fig. 4.—Chrysanthemum, Walter Hunnewell.—See page 16.

whom I entrusted the work failed to notice that they were both budded, four or five inches from the ground, on what have proved to be tender stocks. It is needless to say that no grafted or budded tree can survive its stock, and unless buyers are warned to plant them very deep the trees of this Apple will be denounced, when put upon the market, as a fraud, so far as its supposed hardiness is concerned. Such high working is

In nursery work this principle has long been well understood by growers in the iron-clad region; and it is this necessity which has led to the practice, in root-grafting, of working long lions on short roots. The subject has been debated in our horticultural publications and meetings with a good deal of energy, and both nurserymen and orchardists outside of the cold north have taken part in the debate, not always with a

clear view of the entire situation. The matter of this so-called "whole-root" grafting, which really means the use of a longer or shorter top-cut of the root on which to work the cion, was started by a Missouri nursery firm, and could hardly have originated where the necessity of putting the tender root as far beneath the surface of the soil as possible is fully comprehended.

The necessary depth for planting out grafts of iron-clad varieties, worked on roots grown from seeds of tender varieties, can only be gained by the use of long cions, and these must extend far enough below the surface to insure sufficient moisture about them to cause the putting forth of strong roots from the cion itself. Success in this depends upon the height of permanent moisture in the soil. In northern New England so great a length of cion is not needed for this purpose as in many parts of the west, and especially in the dry states like Kansas and adjoining portions of Missouri.

But why is so little said yet about using iron-clad seedlings for stocks? Is there any good reason to suppose that the seedlings of Oldenburgh would not be as hardy as their parent? Have we not sufficient ground for believing that if we plant the seeds of the iron-clad Apples of north central Russia, the seedlings grown from them will be sufficiently hardy to be used and planted in the same way as more tender seedlings are in a milder climate? Not only for root-grafting, but for budding, will not Oldenburgh-seedlings serve and answer all our needs in the cold north? I read nearly everything I can get hold of on these matters, and have sets of the proceedings of all the horticultural societies of the cold north; but I do not recall any discussion or even mention of so important a question.

It is very doubtful whether our American iron-clads, which are, so to speak, mere accidents, could be reasonably expected to give us reliable seedlings for this purpose; and I should not care to plant seeds of Astrachan, or any apple of south Russia, to grow stocks for budding, or even grafting. But I believe it is fully time to begin some exhaustive tests to settle this not unimportant problem. Some may ask why so little has been done about it. I can only say, for myself, that as I have a ready sale for all my Russian apples, and never have ground any for cider, I have always sown the ordinary Apple-seeds obtained from dealers. But I mean to keep the matter in mind, and I write this to urge the same course upon others.

Newport, Vt.

T. H. Hoskins.

Anthracnose in Bean-seeds.

I HAVE received a letter from a large seed-house asking for information concerning the anthracnose in Bean-seeds, and Mr. Lyon, in his article, "Damping Off," in GARDEN AND FOREST, vol. iii., p. 599, virtually requests the same thing.

The fungous disease of the Bean has been known for many years, and my purpose here is only to record a few observations and suggest a feasible method of avoiding serious trouble.

The fungus (*Colletotrichum Lindemuthianum*) most frequently attacks the pods of the bean when they are partly grown, forming deep dark pits and lessening the yield. The fungus spreads rapidly, from pod to pod, in the market-place, and a spot may be established by inoculation upon an otherwise healthy plant in thirty-six hours. Whatever may be the true life-history of this fungus, it is certain that it can exist from one season to another in the mature beans themselves, and when these diseased seeds are planted the best possible condition is given for perpetuating the disease.

Beans of various sorts were examined, and a large percentage of some of the Wax sorts were found defective, particularly in the region of the eye. Instead of the natural color and plumpness, the coat would be brown and wrinkled. When such beans were split open the rusty appearance would be found extending half-way through the seed. By placing such imperfect beans in a dish in a moist chamber and keeping them moist, a rank growth of the fungus quickly developed upon the diseased portions and rapidly spread over the healthy portion of the seeds. The spore-patches were often so abundant as to almost completely cover the surface of the beans, and the spores developed in countless numbers. As a rule, bacterial fermentation soon after set in, and the small heaps of halved beans became offensive masses of decay. This only shows that the beans are rich in those substances enjoyed by the fungi, hence the rapid development of the anthracnose. A more careful examination of the diseased beans when first split and before they had remained for a time under favoring conditions, showed that the surface in some instances was already studded with the spore-masses, thus demonstrating that the

dry beans in the market and seed-stores may be infested with the disease.

The next point was to note the behavior of the seedlings. Those from good seed came up promptly and looked well, almost without exception, but only half of the diseased seed germinated under the same conditions, and the plants were sickly and spotted with the disease. Several of the plants were so badly infested that there was scarcely a healthy place to be found from the root to the leaves. From such plants it was an easy matter to introduce by a needle the infection into the tissues of a healthy stem.

The next step was to test the value of treating the diseased seeds with some fungicide, and it was found that the best results were obtained by soaking the seed for one hour in a solution of three ounces of the carbonate of copper, one quart of ammonia-water, and four and a half gallons of water—that is, five times the strength of the standard solution for grape-rot. From comparative tests it can be safely stated that the product from untreated seed was diseased four times as much as that from the copper-soaked seed. These experiments teach that one method of reducing the disease is to have seed that is free from the anthracnose. This cannot be ascertained without a microscopic examination, but a brief soaking in a fungicide, while it does no apparent harm to seeds free from the disease, has the power of greatly reducing the amount of it in plants from infected seed. Unlike spraying plants in the field, the soaking of the seed is a simple and very easy matter, done once for all at the expense of a few cents for an acre; and, therefore, this method is recommended wherever the disease threatens the crop.

Rutgers College.

Byron D. Halsted.

The Carnation Rust.

THE note by Professor Halsted on the Carnation Rust (vol. iv., p. 596) has called forth many letters, from which it appears that this fungus, *Uromyces caryophyllinus*, has already

Fig. 5.—*Uromyces caryophyllinus*; pustules on the stem and leaves of a Carnation.

obtained a very wide distribution in this country. It is said that some of the growers along the Hudson River have known of this pest for three years. Professor Galloway, of the United

States Department of Agriculture, writes that rather more than a year ago he had received from Professor Taft, of the Michigan Agricultural College, Carnation-sprigs badly affected with this fungus, and he then wrote that, so far as known, *Uromyces* had never before been found in the United States. He added that it might prove troublesome if it once gained a foothold, and therefore he thought it well to call the attention of florists to it. We learn of it in Michigan, Ohio, the vicinity of Philadelphia and other parts of Pennsylvania, and in the neighborhood of Boston.

Little can be added to what has already been said as to the effects produced on the plant by this fungus. In order to make it easy of identification we herewith reproduce two figures from Briosi and Cavara's work on the *Fungi of Cultivated Plants*, which Professor Galloway has been kind enough to send us, so that all growers may be able to identify the disease. On page 18, Fig. 5 shows a sprig of Carnation affected with the rust, with the pustules appearing on the leaves and stem. A thin cross-section through a leaf-pustule is represented in Fig. 6, from which it will be seen that the spores (a) are borne on short stalks.

Fig. 6.—*Uromyces caryophyllinus*.—See page 18. Cross-section of pustule. a, Spores.

Where Carnations are kept cool and dry—that is, with abundance of light and air—it does not spread so rapidly nor grow as vigorously as it does under other circumstances. It is worse in those portions of the greenhouse where the pipes are hottest. Some varieties are much more susceptible to the disease than others. Mr. E. G. Hill, of Richmond, Indiana, finds that the heavy-growing and fleshy-leaved varieties suffer the most. Mr. Lonsdale advises that great care should be taken in selecting cuttings for next year's plants, and these should be treated to a dip in some fungicide, like a weak solution of the Bordeaux mixture, before they are inserted in the propagating-sand, and they should be sprinkled once or twice a week afterward to keep it in check. Of course, such ordinary precautions as picking off the diseased leaves, removing diseased plants, and keeping young plants as far as possible from old ones which are supposed to be infected, should not be neglected. One grower writes that he fears that the Bordeaux mixture will poison his soil, a possibility which has been suggested by Colonel A. W. Pearson in this journal. But Colonel Pearson also suggested that the copper mixture could be used for Grape-rot in a much more diluted form, and it is not improbable that experiment would show the same to be true in the case of this fungus. Besides this, it is not likely that the soil in the pots or benches would become sterilized by the cautious use of copper within three or four years, even if there was a genuine danger from this source, and as greenhouse soils are frequently changed, this danger should not forbid the use of the copper mixtures.

Fuchsia, Dunrobin Bedder.

IT is a great gain to secure for the garden a dwarf hardy Fuchsia, free, compact and useful either as an edging to large beds or by itself to form a distinct group on the grass. We have such an acquisition in the variety Dunrobin Bedder, a form of the popular *F. Riccartoni*, one of the hardest and most beautiful of Fuchsias; it was raised by Mr. Melville, who has charge of the interesting gardens at Dunrobin Castle, Sutherland. He hybridized *F. Riccartoni* with the greenhouse varieties, and out of about one hundred seedlings which he managed to bloom this was selected for its unusual dwarfness, compactness, vigor and freedom of bloom. I first noticed it in the gardens of the Royal Horticultural Society, Chiswick, where it had been sent for trial, and was impressed by its distinctness and beauty. It is perfectly hardy here—at least it has withstood the trials of ten winters in Sutherland. In seasons of exceptional severity the plants are cut down to the ground, but not killed, and they grow freely again with the quickening

warmth of spring. Its great charm is as a bedder, and it may be used for edging or as a groundwork to a bed of taller Fuchsias. Mr. Melville propagates this Fuchsia in the same way as ordinary bedders—that is, by putting in several cuttings in a five-inch pot in August or September. To obtain an early display of flowers the cuttings are potted off singly in the following March, and a quick return in the way of bloom is secured. The old specimens will also provide a feast of color if they are lifted before touched by frost, placed closely together in a cold frame, and pruned a little in the late spring before again occupying their place in the garden. Many uses for a dwarf, hardy, vigorous plant like this will suggest themselves, and we have seen it used to advantage as a window-box plant, also in large vases.

Chiswick, England.

Vincent Cook.

Hybrid Violas.—Now that the owners of gardens are making preparations for the spring and summer allow me to suggest the trial of hybrid Violas, or, as they are sometimes known, the Tufted Pansies, which do not seem as much cultivated as their merits deserve. These plants are hybrids of various alpine Violets with some admixture with the florists' Pansies. While some of the varieties have the tufted habit which has led to the naming of the race, this habit is not universal, and most growers favor the "Hybrid Violas" as a more correct name. The present race of Pansies is the result of long-continued selection, having always in view, as one of the main points, the increase of size. While mere size is not objectionable, a large proportion of modern Pansies are coarse, with colors very much blurred or run. Of course, there are fine collections of Pansies with pure clear colors well defined and very satisfactory in every point of view. The hybrid Violas, while much resembling Pansies in foliage and growth, are quite distinct in effect, having a beauty of a daintier order. The flowers, similar in form to good Pansies, are usually about half the size, and are, in good varieties, without a trace of coarseness in texture and of the most satisfying purity of color, to which good qualities many of them have in addition a delicate yet distinct fragrance. They are very free-flowering and make capital bedding plants. They can be planted out as early in the season as the ground can be made ready, being as hardy as the Pansy. They may be secured from any English hardy-plant nursery, and it is well in ordering to arrange for their coming by mail, a much surer plan for soft plants than the express, with the long delay at the customs. Some of the best kinds in cultivation are Countess of Kintore, Quaker Maid, Ariel, Skylark, Violetta, Countess of Hopetoun, Duchess of Sutherland, Sir Joseph Terry, Archie Grant, Puritan, Ardwell Gem, King of Yellows.

Primula floribunda.—This Himalayan Primrose is one of the brightest of greenhouse flowers, and much more attractive in color than *P. obconica*. Nothing brightens up a garden as much as masses of good yellow flowers, and the color of this Primrose is of the clearest deep golden hue. As its name implies, it flowers freely and continuously. While the scapes are not as hard and rigid as those of *P. obconica*, it is useful for cutting for dainty flower-arrangements. It is readily grown from seed, which germinates rapidly, and seems to thrive in a moderate warmth and not too moist an atmosphere. Some plants in cooler quarters have not been quite happy, and probably from fifty degrees to sixty degrees Fahrenheit is a suitable temperature. The type of this plant has small flowers, but there is a variety with large ones of the same color. It was with regret that I threw out *P. obconica*, after becoming a victim to its irritating spicules, though, curiously enough, I had grown it several years and had not been affected till attention was called to its properties. Aside from this one fault, it is one of the most valuable minor plants, being always covered with pretty, useful flowers. In the hope of filling its place, I am watching carefully a pan of hybrids, *P. obconica* × *P. cortusoides aincena*, from which, I am assured, there will be plants with larger flowers and a range of colors from white to red. This seems a promising cross, though there is more than a suspicion that there will be some of those dreary blue-reds of *P. cortusoides* to weed out. My principal wish is that the cross may ameliorate the structure of the foliage so that it may prove innocuous. With such foliage and flowers larger than the type there would be a gain indeed.

Elizabeth, N. J.

J. N. G.

Galanthus nivalis, var. Octobrensis.—This Snowdrop flowers here from the beginning of October until November, and is then succeeded by *Galanthus Corcyrensis*, the latter opening the first flowers in the first week of November, and continuing for about six weeks. There is not much difference in the flowers,

only the segments of *G. Octobrensis* are a little narrower than those of *G. Corcyrensis*; the principal difference is in their time of flowering, the latter being always four weeks later. We cannot force *G. nivalis*; but when these autumnal sorts have become more plentiful we shall have Snowdrops in bloom from September to April, and as people are always fond of popular flowers at an uncommon time they will find a ready market. Twelve bulbs in a comparatively small pot will make a beautiful group. I may add that by proper treatment and careful selection of seed, they will, in time, improve in form and size, so that the flowers of my best seedlings have segments of over an inch in length.

Baden-Baden.

Max Leichtlin.

The Forest.

Management of the National Forest-reservations.

AT the late meeting of the American Forestry Association, Mr. B. E. Fernow, chief of the Forestry Division, Department of Agriculture, read a paper on this subject, from which we make the following extracts:

The objects for which National Forest-reservations can reasonably be asked are mainly of an economic and not of an æsthetic nature.

The situation briefly is this: The major part of the public domain, which was wooded, has been disposed of without regard to the value of the forest, either as marketable material or as a protective cover. A large part has been and is being wantonly wasted and destroyed by fire every year. Now it is proposed to change this policy. Instead of holding this property in the hands of the Government for eventual disposal, it is intended to withdraw at least parts of it from entry and to keep it in permanent possession and control of the Government, with proper recognition of its special value as being wooded.

The law of March 3d, 1891, authorizes the President to reserve wood-lands, and by public proclamation to declare their establishment and fix their limits.

As far as the law goes, the object of the proposed reservations is left undefined, as well as their number or extent. I may, therefore, only define the objects for which at present they are probably authorized and what the aim and the methods of their management, separate from that of other public lands, should be.

While in the minds of some, inspired with a general love of the woods, the whole forestry problem is more or less a sentimental matter, and the uppermost idea is, that to stop vandalism by the axe and fire, to preserve natural scenery and to create parks for recreation and hunting-grounds, is the aim of the forestry movement, and of these reservations in particular, I must protest against placing these ideas in the foreground. It is perfectly legitimate for a civilized nation to set aside and preserve as national monuments such areas as the Yosemite Valley, the Big Tree groves and the wonders of the Yellowstone Park; but to withdraw large areas of land from private occupancy will be warranted only when well-substantiated, economic reasons for such withdrawal exist, and objects of a more important communal interest are thereby to be obtained.

These objects I consider to be twofold. First, to assure the communities growing up with wonderful rapidity in our western country of a continuous supply of wood material; second, to assure a continuous forest-cover of the soil on hill and mountain-slope for the purpose of stable soil—conditions and equable water-flow. Just as the first of these economic objects can be attained without frustrating the last, just as the forest can be made to yield continuous supplies without destroying it, just so may the æsthetic and sanitary objects be satisfied by the way without need of curtailing the economic ones. These economic objects, namely, continuous supply of timber and such forest-conditions as will secure favorable water-conditions, can alone be considered as the objects of management to be discussed here.

The difficulties which stand in the way of a management that is to secure these objects are of two kinds, namely, those opposed by nature and those opposed by man.

Excepting on the western slopes of the Pacific mountain-ranges, the climate of the largest part of the territory concerned is such as to render forest-management for reproduction and reforestation difficult; this difficulty has been increased by the action of man in barring slopes and burning the fertile leaf-mold, thus reducing the chances of germinating seeds and young seedlings. Difficulties of this nature can be removed only after careful study and experiment in the

field. We will, therefore, have to start with a simple, common-sense management, and will have to leave the development of better forestry methods to future years, providing only the opportunity of gaining necessary knowledge and experience for the best results.

The main difficulties to be met for the present are those opposed by man.

The social and economic conditions of our western mountain states are peculiar, but they are easily understood and explained when we realize that upon their 1,000,000 square miles not quite 3,000,000 inhabitants are to be found, or only three to the square mile, and if we deduct the population of the cities, a little more than three to every two square miles. This scarcity of population, together with the spirit of independence and self-reliance born and remaining from the pioneer days, when each having single-handed to stake out and defend his own homestead, and to provide for himself and family in the wilderness, was under the necessity of using natural resources, accounts for the prejudice against the curtailment of accustomed and at one time necessary privileges. A feeling of freedom is created in him who finds but little friction with neighbors; he becomes a law unto himself, and government, with which he has but little touch, and which does not understand him or benefit him, appears to him often an unnecessary restriction, and he places the laws of necessity, as he conceives them, readily above the laws of the land.

If this spirit exists in the bona fide settler and citizen, it exists to a still greater degree, bordering on absolute lawlessness, in the irresponsible class of adventurers which a new country always attracts, especially when the laws are either incompatible with existing conditions or are poorly and unsatisfactorily administered for lack of discretion on the part of officers or for lack of proper machinery. We cannot deny that there has been much incompetency shown in the administration of the land, and especially the timber question, by the United States Government, so as to lead western communities to chafe under improper restrictions and to believe a change for the better impossible or impracticable.

To make more intelligible the difficulties arising from this state of things, a brief extract from the paper by Mr. Bowers, presented at the last meeting of this association on the Conditions of Forests on the Public Domains, may be of service.

He says: "Under the act of June 3d, 1878, applying to Colorado and the territories, settlers and others were permitted to cut timber for mining and agricultural purposes from mineral land. Before cutting timber for local use the settler can hardly be expected to sink a shaft or hire a chemist to determine whether the land is in fact mineral or not. He cuts where most convenient for him, without knowing what the character of the land is, and takes the chance of being prosecuted. Not one acre in thousands throughout the region to which this act applies is known to contain minerals, but it is the only act under which timber may be taken by settlers and miners in this great region. Consequently this whole population is forced to steal one of the necessities of life. To the miner and settler of that region the use of timber from local supplies is as absolutely necessary as the use of the water that flows by him, or of the air that surrounds him, and no plan of management which fails to recognize this can ever hope to be successful. The settler, after taking a piece of Government land in the vicinity of the mountains, finds immediate use for timber for the construction of his buildings and fences, and he naturally helps himself. The prospector and miner and the great mining companies have the right to cut timber growing on the mineral lands about them; the railroad supplies itself from the adjacent timber, and the settler can hardly be blamed for doing the same. Oftentimes, as a community of settlers becomes sufficiently large to support it, a small saw-mill springs into being, and the wants of this little community are supplied by the local mill, drawing its timber from the Government land without any authority whatever. Both of these classes, the settler and the local mill man, are then criminals under the law, and are also liable in a civil action for damages, but before a local jury prosecutions almost invariably fail.

"The sympathies of the entire community are always with these depredators of the public timber, and quite often the jurors themselves have been freely using such timber. Indeed, it is a matter of the greatest difficulty to induce a grand jury to indict persons who have confessedly been cutting Government timber for years to supply their saw-mills, the product of which is used quite likely by the very members of the grand jury."

One striking difficulty in establishing the reservations themselves is that much of the land that should be reserved is as yet unsurveyed, other parts are subject to prior rights or are

expected to be included in railroad grants. In fact, to make a success of this movement and to establish a thorough-going forest-policy, it will in the end become necessary, not only to reserve all the remaining timber-lands, but also to buy up such interspersed parcels held by private owners as destroy the compactness of the reserves, and thereby impede their economical management.

It is an old experience that the greatest difficulty in breaking up old and introducing new methods comes from the momentum of habit and established usage, and the resistance of the momentum to a change of direction increases with the increase of friction. Hence, to make innovations successful, they must not be made abruptly, but must adjust themselves as much as possible to existing conditions, and be allowed to develop gradually into new systems. The spirit, then, which will oppose any new policy that smacks of restriction, must be overcome by judiciously legalizing such uses as are permissible, and controlling their exercise with the least friction.

To make such a control possible, officers of discretion, tact and, at the same time, strong administrative capacity are necessary, and legislation, devising management, must be content to indicate general principles only, leaving the details to the administrative officers.

The management must provide, (1) proper organization of an efficient service; (2) protection against theft, fire or other damage of the property; (3) regulation of the occupancy and the use of the reservation by citizens; (4) a system for cutting the crop and marketing it according to the needs of the population; (5) reproduction of the crops and maintenance of proper forest-conditions.

The principles which should underlie such management have found expression in Senate Bill No. 1779 of the Fiftieth Congress, and may well serve as a pattern for an administration of less general character.

The modifications, which are necessitated by only a partial reservation of wood-lands into single detached reserves, will suggest themselves. One point needs to be constantly and strenuously insisted upon, which is, that no management can be successful unless it be properly provided with machinery. Without managers there is no management, and without guards there is no protection. Hence a well-organized force of officers is a *conditio sine qua non*. As usual, it is the question of men, not of measures, that presents the real difficulty.

Mr. Fernow then proposed a system of administration of which we only have space to give a mere outline. The reservations should be under a central bureau co-ordinate with the General Land Office and under the Department of the Interior. Each reservation should be controlled by a responsible superintendent, assisted by an adequate force of rangers, each of whom is responsible for a district. Management of forest-property especially requires permanence, and therefore superintendents should have positions during good behavior, and the rangers should be appointed with their approval. As an additional safeguard, inspectors should be appointed, each of whom should have a number of reservations under his charge, and, by visits and otherwise, keep the central administration advised of local needs. In the matter of regulations, provision should be made for restoring agricultural lands to settlers; for giving opportunities to prospect for minerals; for issuing permits for hunting and fishing; and licenses for timber-cutting under proper restrictions. But whatever scheme of administration is devised it must be simple, tentative, capable of development into a more comprehensive system, with the application of finer methods of forestry added as experience shall teach them. Mr. Fernow concluded with the hope that there would be no need of inaugurating a government for detached reservations, but that Congress would pass a bill for the withdrawal of all timber-lands from entry and for their general administration, since nothing short of such a measure would satisfy the needs of sound forest-policy.

Do Varieties Run Out?

To the Editor of GARDEN AND FOREST:

Sir,—I have read with interest Dr. Hoskin's article (see vol. iv., p. 593), but I can hardly endorse his view that the weak varieties may run out even under favorable conditions. The decision of this question seems to hang upon the influence of propagation by different methods. In the economy of nature there are several methods of multiplication, that by seeds being more nearly universal, but I cannot see why it is more natural than increase by runners, as in the case of the Strawberry and some other plants. If we lay aside the great changes

which have occurred in climate and other conditions during the past ages of the world, and which are likely to occur again, I suppose that no one will hold that seedlings of a Chestnut or an Oak or any other tree will have their longevity diminished on account of the old age of the parent tree. What is the ground for supposing that a plant, produced at the end of a runner, is more likely to feel the effect of the wearing out of the original plant than is a seedling?

In the instance of a Strawberry the plant that forms at the end of a runner and roots in the soil is soon capable of sustaining an independent life, as a new edition of the original variety, and ready in turn to throw out another runner for successive editions; and I can see no reason why the plant at the hundredth thousandth remove from the original differs in vigor or longevity from seedlings at a later removal. Some plants increase by throwing up suckers, others from bulbs and rhizomes, others from the tips, and these plants seem to have the same vigor as seedlings. Now, why should multiplication by cuttings or grafting differ in vigor from individuals produced in any other way? The entire practice of horticulture is based on the theory that these cuttings produce new plants, which are essentially individuals, with a life of their own and with no dependence on the parent.

As to the practical bearing of the question Dr. Hoskins says that the Fameuse Apple is not doing as well now around Montreal as it formerly did, and leaves us to infer that this may be the possible result of the running out of a weak variety. It may be that local causes produce the difference, for the Fameuse here is more vigorous, and quite as productive, and gives larger fruit than it did in Massachusetts thirty years ago. The trees standing in nursery-rows show no inherent weakness. Wilson's Albany Seedling Strawberry has often been quoted as an example of running out, but it is still grown in many places, and wherever it is said of the Wilson that "it does not do as well as it used to," there may be sufficient reason for the change. Strawberry rust was unknown in this section a few years ago, and the Wilson is peculiarly liable to its effects. We are, therefore, growing varieties which are less susceptible to injury from this pest. Whenever a fresh importation of plants is made from some distant place where this rust does not prevail they show all their early vigor. On the other hand, the Pearl, which has only been in existence a few years, and which is a vigorous variety under favorable circumstances, rusts so badly that it is a total failure in four cases out of five.

Dr. Hoskins and many others seem to think that a variety with a weak constitution is liable to run out. Of course, if naturally weak, it would be more susceptible to unfavorable conditions, but only so far as these conditions extend, and this is no proof that any given variety has a term of existence, and when the destined time for its death comes that the variety will cease. I have never yet seen any proof that any good variety with sufficient vigor to carry it through a course of propagation up to maturity could not be made to live indefinitely, if the surrounding conditions are in all respects equally good with those under which it was produced.

Hamonton, N. J.

William F. Bassett.

[This is one of the mooted questions in horticulture, but facts which seem to have weight on one side or the other are always interesting. It is argued by some that since every seed has two parents, seedlings are more likely to inherit the power of adapting themselves to a wider range of conditions than plants propagated by other methods. On the contrary, many plants, like Horse Radish and the Banana, have been cultivated for generations without the use of seed.—ED.]

Winter Vegetation on Florida Sand-dunes.

To the Editor of GARDEN AND FOREST:

Sir,—On the sand-dunes at Pablo beach, seventeen miles east of Jacksonville, the Water Oaks and Live Oaks are shrubs of from two to four feet in height, their dark greenness being emphasized and enlivened by the pale and radiantly forked fingers of the omnipresent Saw Palm. Around clumps of these three, Black Nightshade and a Ground Cherry, *Physalis viscosa*, were, with the very common *Heterotheca scabra*, mildly flowering this mid-December day.

Under the Saw Palm's leaves the brown and dead stems of a *Eupatorium* were observed at many points, and where the sun has fairer play a pale, brownish gray *Croton*, *C. maritimum*, a prostrate Rock Rose, *Helianthemum Arenicola*, and an equally low but grayer evening Primrose were evidently

enjoying life. This last is *Oenothera sinuata*, var. *hemifusa*, and here exhibits two shades of hoariness and two pronounced variations in the tooting of its leaves. The little, clinging, short-petioled and pure white-flowered *Oldenlandia rotundifolia* seemed to be making an heroic effort to save the sand-hills from removal by the winds of ocean, but the size of its spread seemed hardly likely to give its scheme any large measure of success. It surprised me to find this diminutive plant so high on the dunes in soil apparently so dry. Upon these same inclined and shifting surfaces a spreading composite, supposed to be of rather recent introduction, occurs frequently. This is *Acanthospermum xanthoides*, with heads which, when their fruit is mature, resemble minute, especially crabbed specimens of the five-rayed star-fish. This was in flower, as was also another equally modest member of the same order, *Eclipta erecta*. With the *Eclipta* were the strict-stemmed and blooming *Samolus floribundus*, the prostrate and also blooming *Herpestis Monniera*, and the creeping *Lippia nodiflora*, not yet showing its heads of flowers.

The *Lippia* and *Herpestis* had dipped into the white-lined, quietly flowing sulphur-water brooklet, while following them and holding above their stems its peltate leaves appeared the umbelled marsh Pennywort, *Hydrocotyle umbellata*, as careless of the season set by the manual for exhibiting its flowers as many another of the lower-growing species. I brought away with me the dead calyx-decorated stems of *Teucrium Canadense*, but had rather have secured a single stem of the Youpon, densely set with drupes, than aught else. This seaside Holly covered perhaps more space than any other one plant growing back of the dunes, but it lacked just here its handsome red berries, not a simple specimen in fruit being seen by me during my several hours' stay.

Japanese Art in the Arrangement of Flowers.—I.

The Flowers of Japan and the Art of Floral Arrangement. By Josiah Conder, F.B.I.B.A., Professor of Architecture and Architect to the Imperial Japanese Government. With illustrations by Japanese artists. Tokio, 1891.

This most beautiful, most novel and interesting book is of quarto size, and is illustrated by fourteen full-page plates in color and forty in black and white, as well as by many cuts in the text. It is handsomely printed and is charmingly bound in parchment covers decorated in color. All the drawings, which include landscape and garden views with figures, are excellent examples of Japanese draughtsmanship and printing, and no more need be said to prove their excellence. There is only one fault in the make-up of this admirable volume: the silk strings which bind the sheets together are inserted so close to the edge of the text that it is difficult to open the pages wide enough for perusal.

In his preface Mr. Conder says that his book is the result of the interest excited by a paper on the subject which, in 1889, he published in the *Transactions of the Asiatic Society of Japan*. He has now supplied a much larger amount of information, which gets triple value from its profuse illustration, but has cast it in a simpler shape. The subject is so unfamiliar to most readers and Mr. Conder's treatment seems so detailed to western minds that it is impossible to review the book in any limited space. Every chapter is significant; almost every paragraph is suggestive; and an attempt to mark passages for quotation would leave no stretch of margin untouched. Of course, some of the facts which Mr. Conder makes plain have been noted in a more or less casual way by a hundred travelers in Japan. But none of them, perhaps, has ever before been so clearly set forth, and nothing previously published in our language approaches this book in its explanation and illustration of the whole fascinating and complicated subject; but how complicated, how subtle, emblematic, poetic, religious, and even philosophic and historic, are the ideas with which it is inseparably connected in the Japanese mind, one would never fancy until he has had Mr. Conder for his guide.

Mr. Conder makes no attempt, he tells us, "to discuss the different schools of flower-design, each of which lays claim to be the only true exponent of the art, and to possess secrets unknown to rival teachers. A study of the different theories of these schools, and of designs illustrated in their published works, shows that the principles of arrangement followed deviate in no important points." Three chapters are devoted to the flowers of the country, classified as those of spring, of summer and of autumn. In the first we read of Plum-blossoms

and Cherry-blossoms—of the various ways in which they are cultivated and are enjoyed. The second tells us about the Wistaria, the Iris, the Pæony and the Lotus; and the third about Chrysanthemums, Maples and the "seven plants of autumn," by which term are meant the *Lespedza*, the *Morning-glory*, the *Eulalia Japonica*, the *Valeriana villosa*, the *Valeriana officinalis*, the *Pueraria Thunbergiana* and the *Carnation*. These, we are told, though comparatively ineffective individually, are prized at a season when flowers are rare, and gather "importance and interest in combination." But much the larger part of Mr. Conder's book is absorbed by the eight chapters on Floral Arrangement devoted to Flowers According to their Months, History and Theory, Lineal Distribution, Selection of Material, Flower Vessels, Position of Flowers in Rooms, Ceremonial and Etiquette, and Practical Examples.

"The arrangement of cut-flowers in vessels of various kinds," says the author in an introductory passage, "has become with the Japanese a decorative art of considerable refinement, compared with which the western methods of floral composition appear but haphazard combinations. The bouquet, the wreath and the garland, all depending for their beauty upon the close massing of blossoms and greenery in luxurious confusion, bear no resemblance whatever to the more austere and open combinations of the Japanese. The fact that many of the most charming flowers of the country are those of trees, the blossom-clad twigs of which it is impossible to arrange in closed and rounded masses, may in some manner explain the open, lineal character given to floral designs; but the same treatment is applied equally to flowering plants and grasses which lend themselves more easily to the European method of grouping. The peculiarity of treatment noticeable in these flower-arrangements, is closely connected with the Japanese manner of observing and enjoying floral nature. Whereas the eastern amateur devotes his attention mainly to the blossoms, the Japanese lover of flowers bestows his admiration on the whole character of the plant or tree producing them. The rugged nature of the Plum trunk, with its straight, stiff shoots, or the graceful sweep of the branches of the Weeping Cherry, are inseparably associated with the beauty which the blossoms themselves possess. The lines of branch and stem, the form and surfaces of leaves, and the distribution of buds and blossoms, all receive their full share of attention. The loveliest buds and blossoms torn from their stems and crushed together in a mass, with ferns or other greenery between them, convey to the Japanese mind no idea of floral art or beauty. The art under consideration is, in fact, based upon the representation, more or less conventional, of floral growth; and principally for this reason the compositions are made to assume an open character, in which the individual forms of branches, stems, leaves and flowers are all clearly expressed. The Japanese term 'Hana,' translated as flower, has, in the art of floral arrangements, a much wider signification than its English equivalent. Among the so-called Flowers of the Season are included certain evergreens and other flowerless shrubs and trees, some of which hold very high floral rank. The Pine and Bamboo, for example, both occupy a very important place in what are called Flower-arrangements. And the Maple, with its reddening leaves, is used as one of the principal flowers of autumn.

"Seasonableness in the choice of material is one of the leading principles which guide the designer. The luxurious taste for designs, as associated with the idea of rarity, is diametrically opposed to the rules of the art under consideration. Flowers blooming out of their proper season are, with very few exceptions, rejected for floral compositions, which are intended, in a manner, to be expressive of the particular period of the year. April blossoms used in any other month would appear to the flower artist as incongruous and out of place as would be winter clothing worn in summer-time. It therefore naturally follows that a proper cultivation of the Floral Art requires a thorough acquaintance with the nature and growth of all trees and plants employed; and even a close observation of the varying characteristics of the same plant during different seasons, in the case of those which are common to several months. The Flag, or Iris, for example, which is common alike to certain months of spring, summer and autumn, has a peculiar bend and vitality in its leaves, and a different length and vigor in its flower-stems, at the various periods of its growth; these distinctions are all kept in view when employing this flower in compositions."

To explain what the Japanese artist has to learn before he can begin to practice the art of flower-arrangements, Mr. Conder then gives long lists of the plants appropriate to the

different months of the year, and notes those which are suitable for felicitous occasions and those which, on the other hand, are called "ominous."

"Considerations of good or evil luck," he says, "enter largely into the choice of flowers for floral arrangements, especially when employed as decorations for occasions of rejoicing." Those which are reputed to possess poisonous properties, even if this be in their roots alone, are objected to at any time, and all flowers having a strong odor are considered unsuitable for placing before guests, a fact which certainly seems strange to the western mind. The Japanese, it may be said, do not feel as we do that the odor of a flower adds to its attractions from the point of view of sentiment. Mr. Conder then shows that the art of floral composition consists of combinations of two or more kinds of growth, and that in these combinations, not only as regards the actual manner of grouping, but also as regards the preliminary question of selection, the Japanese artist is guided by rules which to us seem curiously arbitrary and subtle. The fact that two flowers grow together at the same period of the year by no means justifies their being placed together. "Sometimes," says Mr. Conder, "too close a resemblance in form or color is the reason of the objection; in other cases, similarity of species, or of locality of production, leading to redundancy of expression in the composition, is the cause of the dislike. The Peach and the Cherry, for example, being both flowering trees and somewhat similar in character are not considered suitable in combination."

We cannot follow the author through his most interesting chapter, called "History and Theory," where he examines into the origin of the now complex art of floral arrangement, and the myriad meanings which the Japanese read into their arrangements. In beginning his detailed analysis of Japanese flower-arrangements he speaks first of "Lineal Distribution." "The lines or directions," he says, "taken by the different stems or branches form the basis of all compositions. . . . The treatment followed may be likened somewhat to the methods employed of distributing carved foliage in architectural panels. The surface of the water in which the flowers are placed is technically considered to be the soil from which the floral growth springs, and the designer must here convey the impression of stability and strength. However good the upper lines of the composition may be, a weak springing at the base deprives it of life and vigor; for it must be remembered that not flowers alone, but floral growth and vitality, are to be expressed in the designs. . . . In the distribution of the principal lines of the composition from the point of their separation, the artist studiously avoids an equal-sided or symmetrical arrangement, but he obtains a balance of a more subtle kind, which is at the same time productive of a pleasing variety of form. Balance and harmony without repetition is a governing principle in this as well as in other Japanese arts." Many pages of careful description and many outline cuts then explain the careful way in which the Japanese arranges his main stems in a flower-group, the arrangement being sometimes bilineal, sometimes tri-lineal and sometimes five or seven-lined by the addition of subordinate lines to a tri-lineal arrangement. Each of these schemes may be infinitely varied, but stems are never grouped together in a careless manner irrespective of an underlying lineal idea. Most arrangements are designed principally to be seen from a point of view immediately in front, yet, we are told, they are not the flat arrangements which might at first sight be supposed from explanatory drawings, especially in the more complex compositions; a pleasing variety is given at the back and sides as well, and their effect, when regarded from these points, is to some degree taken into consideration.

"Certain errors," says Mr. Conder, "in arranging the lines of floral designs, are pointed out to be strictly avoided. Some of these are called Cross-cutting, View-cutting, Window-cutting, Lattice-cutting and Parallelism, which names sufficiently indicate the effects produced, and the reasons why they are to be condemned. In many compositions one of the principal lines is allowed to droop conspicuously at one side, and is called a Streamer; but it is a fatal error to use a Double Streamer—that is, to insert a drooping branch on each side of the same composition."

Bulletin 34 from the horticultural division of the Cornell University Experiment Station is devoted to the Dewberries, several varieties of which have within late years come into prominence. Since the histories of fruits are soon lost and definite knowledge of their methods of variation and degrees of improvement become impossible, we are glad that a record of this fruit should be made thus early in the history of its

cultivation, and we agree with Professor Bailey that it is a great misfortune that we cannot refer to similar reports on other native fruits, such as Blackberries, Raspberries and Grapes. In common speech, the word Dewberry is applied to any creeping Blackberry, but the true Dewberries are distinguished from the Blackberries not only by their trailing habit, but particularly by their inflorescence, which is cymose, the centre flower opening first, and the flowers few and scattered. In the Blackberries, on the contrary, the clusters are essentially corymbose or racemose, the lower and outer flowers generally opening first and the flowers carried in dense clusters. Another difference is, that the Dewberries are propagated from tips, while the Blackberries propagate by suckers.

Dewberries, as cultivated, represent two distinct species of the Bramble or *Rubus*, the first of which is the northern Dewberry (*Rubus Canadensis*), to which type belong the varieties known as Windom, Lucretia's Sister and Geer. Under this species are two sub-types, to one of which belongs the Lucretia, botanically recognized as variety *roribaccus*, and to the other sub-type, the variety *invisus*, belongs the Bartel or Mammoth, General Grant and Never Fail. The second species is the southern Dewberry (*Rubus trivalis*), to which belong Fairfax, Manatee, Bauer and Wilson's White. Since these species are quite distinct, it is reasonable to infer that different management should be used in the different classes, or, at least, that various results will be obtained from their cultivation.

Professor Bailey adduces a large mass of testimony from various sources, which brings out the peculiar merits of the Dewberries as cultivated fruits as well as their peculiar demerits. Their good points are earliness, large size, attractive appearance and the ease with which they can be protected in winter. Their quality is a matter of question. In some places, and to some tastes, they are delicious, rich and spicy, while other judges call them flat and flavorless. The disadvantages in the cultivation of Dewberries are the failure of the flowers to set, the formation of nubbins, or imperfect fruit, and the difficulty of picking the fruit. There is reason to believe that pruning and thinning the canes would tend to obviate the first two difficulties and to make the plants productive, but this is not known positively. The labor and unpleasantness of picking may be avoided by training the plants on a rack or trellis, and by keeping them well pruned.

The plants are generally set about the same distance apart as Blackberries—that is, in rows seven feet apart and three or four feet apart in the row, and the canes are allowed to lie on the ground, and are headed in when they reach about three feet in length. A mulch of straw beneath the canes keeps the berries clean and renders picking pleasanter. A wire trellis, like a Grape-trellis, or various kinds of racks may be used, upon which fruiting canes can be tied, and for amateur cultivation, at least, some such upright training seems to be advisable. Only four to six fruiting canes should be allowed on one plant. Some varieties, particularly the Windom and Bartel, appear to do best when the fruit is shaded.

Twelve varieties of Dewberry have been named and more or less disseminated during the last twenty years. Of these, four (omitting the Mammoth) have gained more or less prominence, and are found to possess decided merits in certain places. This is a fair proportion of good varieties to inferior ones, as indicated by the annals of other fruits. Many persons have found the cultivation of this berry profitable, and this is evidence that the fruit is an acquisition. But it has not yet found general favor, and it is hardly probable that it will ever become a rival to the Blackberry in popularity.

The varieties which enjoy most prominence are Windom, Lucretia, Bartel and Manatee. The Windom possesses promise for the north-west, of which it is a native. It has not yet been tested to any extent elsewhere. It appears to demand partial shade for the best success. The Lucretia has been found to be a desirable and profitable fruit in many places over a large extent of territory, and it is therefore safe to conclude that its range of adaptation is large. Many, however, have failed with it. It appears to be variable, and many of the plants are worthless. It is seriously attacked by anthracnose and by a Bramble rust. Bartel has found great favor with some growers in the west, from Wisconsin to Nebraska (see GARDEN AND FOREST, vol. iii., p. 373, and vol. iv., p. 19, where the plant is figured). It has not succeeded well in the east so far. Some of the variety known as Mammoth appears to be identical with Bartel. Manatee is probably valuable for the south, and it appears to be the most useful form of *Rubus trivalis* yet tested. There are varieties of the southern plant with white berries, for which special merits are claimed.

Notes.

Carnations during the holidays brought from \$2.50 to \$4.00 a hundred, and at these prices the markets took everything that was offered.

We have often spoken of the increasing popularity of Tuberous Begonias in this country, and some photographs just received from the Messrs. John Laing & Son show fields of the single varieties which contain as many as 250,000 plants. We should hardly have expected ten years ago that these plants would soon be grown by the acre in open fields on both sides of the Atlantic.

Some of the poetical names applied by the Japanese to their Chrysanthemums are The Border of the Thin Mist, Companion of the Moon, Shades of the Evening Sun, Beacon Light, Waves in the Morning Sun, The Sky at Dawn, First Snow, Disheveled Hair in Morning Sleep, Star-light Night, Sunny Morning, Leaves and Frost, Golden Dew, Moon-lit Waves and Moon's Halo. This last name we should hardly expect to find applied to a flower of an orange-red color.

The thirty-seventh annual meeting of the New York Horticultural Society will open at Rochester on Wednesday, January 27th, and continue two days. We are acquainted with no similar association in the country where the discussions, especially those on fruit-culture, are uniformly of such a high character. The programme provided for this year is one of wide and varied interest, and the essayists who have been secured are men of the highest rank in scientific and practical attainment.

Among the resolutions passed at the late meeting of the American Forestry Association was one urging upon superintendents of schools in the various states to require that the high schools shall make forestry, in connection with botany, a subject of instruction, and it was further resolved that whereas the interests of agriculture are intimately dependent upon proper forest-conditions, and whereas the Government of the United States has lately made large additional appropriations to agricultural colleges and experiment stations, it is therefore earnestly recommended that forestry be made a part of the curriculum in the agricultural colleges and experiment work in the various stations.

The Albemarle Pippin, which many people consider the best dessert apple, apparently cannot be bought in the markets of any American city, and Americans who want to enjoy this product of the Virginia and Carolina foot-hills must go to London to find it. American Pippins are displayed there in the show-windows of all the principal West End fruiterers; and, like all fruit in London, bring high prices, four shillings the dozen being asked for them last month in the stalls in Covent Garden Market. It is suggested to the growers that it might prove profitable to give Americans an opportunity to purchase this fruit in their own markets. Americans are always willing to pay for superior quality, and those who have not eaten a Virginia Pippin at its best have only a restricted idea of how good an apple can be.

A correspondent of an English paper speaks with enthusiasm of the Christmas Roses at Warwick, where, in one mass, a broad expanse of snowy bloom compelled an expression of admiration. The effect was produced by three hundred clumps of the variety Major of Helleborus niger, all studded with flowers as closely as they could be packed. The blooms were large and beautifully fresh and clean. It is the practice here to grow the plants in a north border, where they remain two, and sometimes three, years. About three weeks or a month before they are wanted in flower the plants are lifted with good balls of earth and placed closely together on the floor of a vinery or other cool structure. A little soil is worked around the roots as the work goes on, and when completed the whole mass is watered through a coarse rose. This washes the soil down among the roots, and leaves the flower-buds clean. As the buds begin to open a little heat is given to lengthen out the flower-stems, as they are better for decorative work when the stems are of good length. After flowering the plants are hardened off, divided, and again planted in the open air.

Death has recently made serious gaps in the ranks of the men who have shed lustre on French horticulture in recent years. At Passy, on the 6th of December, Alphand, the engineer of the city of Paris, died rather suddenly, in his seventy-fourth year. His career commenced at Bordeaux, in 1837, as a civil engineer; here he attracted the attention of Haussmann, who, when in 1874 he became Prefect of the Seine, im-

ported him to Paris to carry out the emperor's plans for the transformation of Paris. He organized the system of street-planting, which has done so much for Paris, and directed the completion of the Bois de Boulogne, constructed the Bois de Vincennes—the people's park of Paris—the Park Monceau and the Park of the Buttes Chaumont, all the squares and promenades of new Paris, and the gardens and greenhouses of la Muette, where the plants used for the decoration of the municipal gardens and buildings and squares are grown, perhaps the best-equipped plant-factory in the world. The success of the great Exposition of 1889 was largely due to the knowledge, taste and marvelous powers of organization of Monsieur Alphand. He made the plan for the grouping of the buildings and the arrangement of the ground, and personally directed all matters of construction and the arrangement of the exhibits. He had brought to this herculean task the experience gained in the organization of two earlier Universal Exhibitions, and the co-operation of a perfectly trained and enthusiastic staff; and yet, with all his exceptional advantages, the apparent ease with which Alphand handled the resources placed at his disposal was marvelous even to those persons most familiar with the perfection of French organization. Under the title of *Les Promenades de Paris*, Monsieur Alphand, many years ago, published a folio volume, splendidly illustrated, in which are described the public works of Paris executed under his direction. Portions of this book, with lists of the trees and shrubs cultivated in the gardens of the city of Paris, were afterward published by Alphand and the Baron Ernouf in a book called *L'Art des Jardins*.

The death of the great engineer was preceded by a few days only by that of Auguste Hardy, the head of the School of Horticulture at Versailles, who, if less known to the general public, was hardly less distinguished in his particular sphere than Alphand was in the larger theatre of his labors. In the interesting and sympathetic sketch of his friend, which Monsieur André has lately printed in the *Revue Horticole*, it is interesting to read that Auguste Hardy's love of horticulture belonged to him by right. His great-great-uncle, named Christophe Hervey, was at the head of the Pépinières des Chartroux at the Luxembourg, from 1752 to 1796. The son of this Hervey was in 1809 entrusted by Chaptal with the duty of re-organizing these nurseries; and a few years later he recommenced in the Luxembourg Gardens the courses of lectures upon the care and pruning of fruit-trees which the Revolution had interrupted. The younger Hervey was succeeded in 1817 in the management of the Luxembourg gardens by Alexandre Hardy, the father of Auguste Hardy, who, naturally enough, determined at an early age to devote his life to horticulture. He became director of the vegetable-garden connected with the palace at Versailles, which he soon made a model of their kind; and when, in 1873, these gardens were converted into the National School of Horticulture, he was selected as the head of the new institution, which has gradually grown and improved under his able management until it has become the best school of its sort in the world. As first vice-president of the National Horticultural Society, Monsieur Hardy was for years the head and moving spirit of that body, and was enabled to render immense services to French horticulture. No man in France appears to have been more loved and honored by his associates, and the influence of his teachings and of a rare and delightful personality was felt far beyond the limits of France through the pupils who had been instructed and trained by him.

As this paper goes to press we learn with regret that Mr. James Taplin, well known as a grower of choice and rare plants, died on Saturday at his home in Maywood, New Jersey. Mr. Taplin commanded respect for his skill in the branches of horticulture to which his life was devoted and for the straightforward manliness of his character. He was in his sixty-first year.

More Forest-reservations.

THE authority to set apart forest-lands as permanent reservations with which the President of the United States was endowed less than a year ago, enjoins upon him the duty of selecting portions of the national domain where it is most desirable to retain the forest-cover. There can be no question, therefore, that he will welcome any suggestions from well-informed and public-spirited citizens in regard to tracts of forest whose preservation may seem most essential to the general welfare. We spoke of it as a gratifying fact in the early autumn of last year that a memorial naming and describing at length five sections which seem suitable for public reservations had been presented to the President by persons of well-known scientific and practical attainments. We gave the descriptions of some of these tracts, with the reasons offered for selecting them. The first was the Flat Head and Marias River Reservation, originally proposed in a bill by Senator Edmunds some eight years ago. The second was the Tulare Reservation, which, like the first, covered an area of 7,000 square miles. It lies on the western slope of the Sierra, and includes the eastern watershed of the San Joaquin River and the streams which flow into Tulare Lake. It was asked for by the California Academy of Science and a convention of the citizens of four of the counties of that state. The Pecos River Reservation, advocated by the Surveyor-General of New Mexico and many other citizens, is on the Las Vegas and Santa Fé ranges. Pike's Peak and its slopes, including an area of some 350 square miles, was the next reservation asked for in order to preserve from extinction the forest-area which now furnishes timber and fuel for 30,000 people, and the water indispensable for irrigating hundreds of thousands of acres of land, besides supplying many communities in a place where the husbanding of water is a trying necessity. The proposed Minnesota Reservation covers some 6,000,000 acres, and includes the sources of the Mississippi and the Red River of the North.

The President has already enlarged the boundaries of the Yellowstone, and has established the White River Reservation in Colorado, with an area of 2,000 square miles. Special agents, too, have been detailed by the Secretary of the Interior to make examinations of the other tracts and report upon their suitability for the purpose indicated. There seems to be a reasonable probability that in some of these cases the President will exercise his power, although to some of them opposition has been made by interested persons. This is especially true of the Minnesota tract; but there can be little doubt that the public opinion of the state would strongly favor the reservation if it was understood that no agricultural land is to be withheld from settlers, and that the people are not to be deprived of the products of the forest. On the contrary, the forest is to be saved from wasting fire and held to furnish continuous supplies under economical management, instead of being stripped at once of its valuable timber and left to be burned over and abandoned.

Another reservation to which we have not before referred at length is asked for by many citizens of North Dakota, including the Superintendent of Irrigation and Forestry. It embraces the elevated lands in Butte and Renville counties, known as the Turtle Mountains and adjacent to the Canadian boundary. This tract consists of a plateau several hundred feet above the surrounding plains, cut near its edges by deep coulees and rising in irregular mountains at their highest point to 2,500 feet above the sea-level. On the borders of this tract are numerous springs, the fountains of streams which water the plains; and many lakes are found in the centre of the tract. Most of it is covered by a mixed growth of Oak, Ash, Elm, Cottonwood, Box Elder, Willow and other trees; but owing to the fires which run through it and the indiscriminate cutting, the forest is in very imperfect condition. It is asked that what remains of this forest may be preserved in order to furnish perpetually wood-products for the surrounding treeless region; to furnish seedlings for tree-planting in the prairies; to retard the melting of the snow and water, and thus prevent spring freshets on the plain; to sustain a water-supply during summer, and to form a protection against the cold winds of the north and the drying winds of the west. It is the only wooded area of any extent in that country which remains in the hands of the Government, and it would be of priceless value as a place of recreation for the people of the neighboring plains and adjacent towns and cities.

At the recent Forestry meeting, among other reservations asked for was one known as "Lost Park." It was advocated by Colonel Ensign, Forest Commissioner of Colorado, and many of the leading citizens of that state. It is in central Colorado, some forty miles south-west of Denver, and forms a part of the water-shed of the South Platte River. It includes about 500 square miles, and ranges from 6,000 to 12,400 feet in altitude above the sea. It is a mountain-region with small valleys, some of the ranges being rugged and precipitous and rising occasionally above the timber-line. The northern slopes of the mountains are generally wooded, and there are small areas of merchantable timber standing there, while the southern slopes are usually devoid of tree-growth. No minerals of any value are known to be within its boundaries. A few entries have been made within the tract, some small saw-mills built, and some cutting has been done for charcoal and other purposes. The settlements along the streams which flow out of the tract need all the water for irrigation that can possibly be secured, and if the timber can be guarded from fire for some years the northern slope will speedily be re clothed with forest.

The Crater Lake Reservation is on the Cascade Mountains, in south-west Oregon, about the source of the Umpqua, Rogue, Klamath and Des Chutes rivers. The whole area to be preserved is 360 square miles. It ranges in height from 4,000 to 9,000 feet above the sea, and includes several lakes at an altitude of 7,000 feet. An extinct vol-

cano, the crater of which is now occupied by a beautiful lake, gives the name to the reservation. Most of the tract is timbered, some of it densely, but on account of frequent fires much of the young growth has been destroyed and it is threatened with speedy denudation. If fire and flocks were excluded the young growth would soon afford a dense shade for the conservation of snow and moisture. The deep snow-falls of winter linger in banks late into the summer, and waters from these melting drifts form the streams which flow in all directions from the region. Senator Dolph introduced a bill for the reservation of this tract in 1889, and his project is endorsed by many of the prominent citizens of Oregon.

There is little danger that the President will be too liberal in the exercise of his power to set apart reservations, and we have to confess the fact that after they are set apart there is no way of defending them from invasion. Mr. Fernow has suggested a plan for their management, and although past experience does not encourage the belief that any such elaborate system will be speedily adopted by Congress, still it is the duty of all who are interested in these matters to work as if all things were possible and to trust in the growing enlightenment of the people of the country on this important subject. We may be nearer a rational forest-policy than we know, but until such a policy is inaugurated it is worth while to take advantage of every possible means to make the best of the situation. Mr. French, in the address from which we quote elsewhere, suggests that a school of forestry be established at West Point, so that officers of the army shall be instructed in as much of the science as is needed to make them competent managers of these reservations. But even without such a school it is to the army that we turn for the protection of public property. Detachments have already been employed in protecting the Yellowstone and the Big Trees. This is the one constabulary force in the country which is thoroughly organized, which has esprit de corps, which is free from political influence, and to which we can look for the courage and trained ability to enforce obedience. It is certainly worth while to consider whether the army is not altogether the best means at hand, not only for the immediate protection of these reservations, but for policing all the public forests of the country until some permanent forest-policy is established.

An Appropriate Decoration.

THE plant of *Helianthus orgyalis*, growing against the wall of a house, as represented in the accompanying figure (page 32), is a charming example of the pleasing effect produced by placing herbage directly in contact with a building to link it to the ground.

This tall Sunflower, with its lanceolate leaves and small single blossoms, has a habit of growth that makes it singularly appropriate and agreeable in such a situation, and the lateness of its blossoming makes it a delightful adjunct to a house in autumn, when earlier flowers have perished. The dwelling in the figure is a long, low building, constructed of white plaster below, and of weather-darkened shingles above. Everywhere it is tied to the broad green lawn from which it springs by ropes and garlands of vines, which climb above the roof of the one-storied studio at one end, and drape the supports of a veranda at the other, in a way which makes the house grow as naturally from the velvet turf as a tree or shrub.

Ivy and Virginia Creeper, the small-leaved flowering Grape, and other graceful climbers weave over the building a drapery of foliage that flows in charming curves to the ground, and adds to the picturesqueness of the whole construction, which in itself has an air of shelter and sweet home-likeness that make one eager to enter its arched doorways, or to linger under the roof of the wide outdoor room, with its mosaic floor and vine-wreathed supports, which forms so agreeable a feature of the dwelling.

Branching overhead are stately Maples, and from be-

tween their straight trunks and low-growing foliage are beautiful glimpses of a bay, with boats and islands, and a stretch of Beverly shore. In the distance, across the lawn, one catches sight of another white villa with patio and balcony, supported by Moorish arches like a home in Spain.

The little Sunflowers by the window, with their lance-like leaves and golden shields, stand like gallant sentinels, ready to protect the household. The rough surface of the plaster bears soft, waving shadows on its snowy surface, and throws the foliage into high-relief. More shadows are thrown by the overhanging eaves over which the blossoms tower, nodding gallantly in the wind, while some of them shine under the gutters, or peep in at the windows, where the irregular panes are set in leaden curves, representing the shape of the Fire Lily, the totem of this artistic home. On the opposite front of the house is the entrance, where on either side and above the shadowy door-way are bas-reliefs modeled in the plaster, some of them representing the same Lily in majestic hues. Here against a curve of the white wall shine the glossy leaves of an Orange-tree, laden with its golden fruit, again suggestive of summer climes, and softer skies than these.

Thus, by vine and herbage, flower and fruit, the dwelling is made to seem a growth rather than a construction, and the value of such connection of house and land is made emphatic. By such means hardness of contrast is banished, and sharpness of outline toned into agreeable mystery, and true picturesque effect obtained.

To produce this unity should be the effort of every one who has even a few feet of land around his dwelling available for planting green things to cling about the foundations, and mask their rigid lines from view. Vines and plants for summer, low-growing evergreens for winter effect, are all beautiful and appropriate, and their use should never be neglected by those who would make their homes attractive and graceful at all seasons.

The Jubilee Year of Kew Gardens.

THE first number of the *Gardeners' Chronicle* for 1892 contains an article on the Royal Gardens at Kew, which have just entered upon their second half-century of useful life. After noting with justifiable self-gratulation that Dr. Lindley, the first editor of the paper, and Sir Joseph Paxton, one of its founders, were largely instrumental in the reorganization of the gardens, the article gives an instructive account of the character of the work of this great establishment. Just now, when an effort is being made to secure a botanic garden for this city, the subject has a special interest for American readers, who ought to have clear ideas about the scope of such an establishment and of the experience and attainments which must be possessed by its directors if it attains anything like a reasonable measure of success. We therefore reproduce the greater part of the article below:

Lindley, in his report to the Government of the day in 1838, said: "A national garden ought to be the centre round which all minor establishments of the same nature should be arranged; they should all be under the control of the chief of that garden, acting in concert with him, and through him with one another, reporting constantly their proceedings, explaining their wants, receiving their supplies, and aiding the mother country in everything that is useful in the vegetable kingdom. Medicine, commerce, agriculture, horticulture, and many valuable branches of manufacture would derive benefit from the adoption of such a system. From a garden of this kind Government would be able to obtain authentic and official information on points connected with the founding of new colonies; it would afford the plants there required without its being necessary, as now, to apply to the officers of private establishments for advice and assistance."

Sir W. Hooker's appointment dated from April 1st, 1841. By his energy, knowledge and courtesy he speedily effected much-needed reforms. His large correspondence with all quarters of the globe, and which had been formerly turned to good account when in Glasgow, were even more fruitful at Kew. On August 9th, 1841, the sub-editor of this journal visited

the garden, and in his remarks at p. 535 of our volume for that year it is recorded that persons, provided they did not touch the plants, were permitted to walk through the grounds without attendance! that there had been a large increase of "respectable company," and that neither plants nor flowers had been injured by the visitors.

Other details are given as to the changes in progress, and especially as to the unrivaled collection of *Proteaceæ*, a group of plants, by the way, better represented fifty years ago than now. The changes effected by Sir W. Hooker were again adverted to at p. 123 of our volume for 1842, where it is recorded that "the well-directed energy of Sir W. Hooker, assisted by a judicious liberality on the part of the Commissioners of Woods and Forests, will speedily place Kew where it ought to be, and once was—at the head of the botanical establishments of Europe."

It is not our intention on this occasion to advert in detail to the further progress of Kew, its great extension, the gradual improvements in general cultivation, and in all departments, under the direction of Sir William Hooker and of Sir Joseph Hooker, and latterly of Mr. Thiselton-Dyer; the new houses constructed, the museums built, the herbaria and libraries formed, the laboratory and picture-gallery established; nor need we do more in passing than allude to the extraordinary literary and scientific activity evinced in the numerous substantial volumes that have emanated from Kew. The Colonial Floras, for instance, were projected by Sir William Hooker. Some are completed, others, like the tropical and extra-tropical African floras, will, we trust, speedily be resumed; while the unrivaled experience and the undaunted energy of Sir Joseph Hooker have brought the Flora of British India nearly to completion.

To the general public Kew is a pleasure-garden merely. It is that, of course; but it is far more. It is, and has been for half a century, what Lindley wished it to be, the centre of botanical activity—activity not only in purely scientific botany, but in garden-botany in particular. It has been a main agency in the collection and diffusion of knowledge of all kinds relating to botany, and has ensured the cultivation and dispersal of economic plants of all kinds in our colonies. We have often had occasion to record, with patriotic pride, the great things for humanity which have been effected through the medium of Kew. Commercial men and practical statesmen are not very likely to feel much enthusiasm about botany as a science—they look upon it, if at all, as a harmless pastime; but when they see—as they may at Kew—what it is capable of and what it has done for the benefit of mankind, they naturally look upon the garden as an institution worthy of their support. The cultivation of Cinchona, Tea, India-rubber, Liberian Coffee, represents only a few of the industries which have been established and fostered in India and our colonies chiefly through the agency of Kew.

All that has been done at Kew in the way of gardening, systematic study, physiology or economic botany, has been done in accordance with the letter and the spirit of the recommendations made by Lindley, but modified and extended by successive directors; and the latest advances—that of federating the several colonial botanic gardens, and that of establishing botanical departments in the several presidencies of India and in the colonies—are in strict accordance with the general plan. Kew has thus long been the centre of botanical energy in almost all departments. Its steady progress and its present condition are matters which excite the admiration of the most competent judges. We have lately had an illustration of this in the glowing testimony as to the condition of and the work at Kew afforded to us in conversation with the directors of two of the most important gardens in the world—that of Paris and the Harvard Arboretum.

In some points Kew still needs extension and improvement. The subject of the diseases of plants, for instance, is vast enough and important enough to demand a separate staff of microscopists and entomologists with a small space set apart as an experimental area. The laboratory and library would be invaluable adjuncts to such a department. Systematic and comparative study of the minute anatomy of plants is also a need of the times that might be largely supplied at Kew. Anatomists would not only find there what they want in the way of material, but they might also profit by imitating the systematic orderly procedures and comparative methods of those who devote themselves to herbarium botany, as it is called. The co-operation of the two classes of workers is a thing much to be desired, and we do not know where it could be better carried out than at Kew.

In the garden itself it is recognized that the cultivation, as perfectly as circumstances will allow, of specimens illustrative

of botanical structure and affinities, and of such as are of horticultural and economic importance, is preferable to the accumulation of so-called complete collections of specimens which cannot be properly grown or displayed. Such plants would be more appropriately housed in the herbarium, while their portraits might find a place in the picture-galleries. For strictly horticultural purposes, numerous and varied trials should be made of new plants to ascertain their value; and not only of new plants, but also of some at least of the vast number at present left unutilized by the gardener. Ordinary bedding-stuff cannot, of course, be dispensed with in a public garden; but we do not want to see at Kew what we can see in any of the parks or in the back-garden of any suburban villa residence. What we see at Kew should be—and to a large extent it already is—of educational value as well as agreeable to the eye.

One of the chief wants of Kew at present is suitable provision for plants requiring an intermediate temperature, between that of the stove and that of the ordinary greenhouse or conservatory, one wherein specimens of many of the economic plants of sub-tropical lands may be grown. Much of this kind of material is already to be found in the smaller houses, chiefly in the T-range; but the plants, owing to the smallness of the houses, and to their growth in pots of no great size, do not convey to the minds of those seeking information their true characteristics, and persons interested in commerce go away from their inspection with feelings of disappointment.

By the completion of the temperate-house, the need we have alluded to will be supplied, and space will be found for most of the economic subjects whose cultivation in our colonies and crown-lands is meeting with so much attention. The plants, being planted out in borders instead of cramped and stunted in pots, will attain to fuller development and show their characteristics more perfectly, and for these reasons the enlargement of this house would be altogether an appropriate commemoration of the jubilee year of Kew gardens.

New England Parks.

THE ARNOLD ARBORETUM.

THE Arboretum is not properly a park, according to the commissioners, but as it is a part of the Boston Park system, I take the liberty to treat it as a pleasure-ground rather than as a school of dendrology, for, indeed, information is here administered so delightfully that one is hardly conscious of being at school at all, and gives himself over to the picturesque effects of this tree-garden, which yearly grows more beautiful and attractive.

Those dwellers in Boston who spend their summers in the country and only drive about the environs of their city in spring and fall, hardly get an idea of what the Arboretum is at midsummer, when all its shrubs are in full leaf and blossom, its trees in their best and fullest foliage, and its evergreens showing their finest and most vigorous color, and at any season when people visit it it would be well if they could be made to realize that this beautiful spot is still in its infancy, that it is slowly growing to perfection, and that all that is unfinished and unsightly about it now is but the deep-laid foundation of a great and enduring monument to the generosity of the founders of this wonderful garden, and to the learning and faithfulness and zeal of its Director, Professor Sargent.

The Arnold Arboretum differs from other arboreta, in that it is the largest space in the world devoted to dendrology as a scientific study, and its collection of woody plants is more complete and satisfactory here than in any of the great botanic gardens of Europe, where the tree collections are simply appendages to their very remarkable assemblage of tropical and native plants. Here 150 acres are devoted entirely to the cultivation of woody plants, that is, trees, vines and shrubs; and these are so carefully prepared and selected, and so skillfully cultivated by Mr. Dawson, the superintendent, that better specimens can nowhere be shown of trees that have only been growing for less than a score of years, while the shrubberies are in great perfection and variety, and the vines beautifully luxuriant.

Its scientific value is so well known and is so ably illustrated in this very paper by writers far more able to cope with it on that basis than I, that it is only necessary now to write of it as a place which everybody in its neighborhood ought to be familiar enough with to enjoy as it deserves, and to suggest that when the early spring tempts the city-dweller to prolong his drive that he should view with more than passing attention this unique and valuable possession of Boston, which he is

apt to pass through carelessly, more conscious of the unfinished grounds than of the plans for a great future which have been so carefully considered in the work about him. For here he beholds not the taste of the day and hour, the rendering of a passing fashion in grouping of trees or massing of shrubbery, but a permanent scientific arrangement, at once fine and instructive, which is to be not only for his benefit, but for that of many generations to come, who shall enjoy the full perfection of that of which he receives but a promise.

Through these entrances so strong and simple, where the plain granite gate-posts are just massive enough to be impressive without pretension, he enters one of the great gardens of the world, to be considered by the future American with the same respect with which the Englishman regards Kew, and the Frenchman the Jardin des Plantes.

There are various ways to reach the Arboretum, but to the visitor by rail the Forest Hills Station, on the Boston and Albany Railroad, affords a convenient approach, and by entering at the South Street gate he is introduced at once to the noblest feature of all—the rocky hill covered with noble Hemlocks, which rises on the left of the entrance—while on the right is another elevation, now crowned with a young and vigorous growth of Hickory, planted Pines, Larches and other conifers, that in a hundred years may make it a rival for the opposite hill, which has borne its stately crown of evergreens perhaps for more than a century and a half.

At whatever season one enters this ancient forest it is venerable and impressive. The hill is a wall of rock in broken terraces, and here upon its northern slope the giant trees lift their great shafts and spread their green branches, even as they must have done when Paul Revere was a boy, and British soldiers patrolled the streets of little Tri-Mountain.

There is no level ground except at the very base of the rise, where a stony brook tumbles along beside a narrow foot-path which you cross a plank to reach. In summer the trees afford cool and grateful shade; in winter shelter and warmth, for the winds are baffled by their phalanx of trunks and boughs and foliage, and cannot penetrate the depths of this forest-asylum.

Following the little woodland-path that skirts the hill you emerge finally upon the broad drive-way, to which it runs nearly parallel. This drive-way, admirably graded, leads by a gentle ascent to the higher ground, bordered throughout its large, gracefully sweeping curves by masses of native shrubs, which, either filled with blossoms or fruit, produce all summer the most pleasing effects of color.

Apparently artless in their growth, there is a perfection in the contour of the whole beautiful border, which shows the most careful supervision. Creepers run from the bushes to veil the edges of the road, and the mass behind leads gradually up to the groups of trees, which are arranged in botanical order, but in such natural groups and blending that the beholder does not realize that what he sees is the perfect and thoroughly contrived section of a finished whole.

First, on the right, come the Beeches, with their spreading branches and serrated leaves. Like all the trees in the permanent plantation of this young garden, they have been started here from seed or bud, and, of course, are still comparatively small; but, as they are to endure for a century or two, they are planted at wide distances, so that there will be ample room for the sweep of their great branches. Even now they are beautiful, with their smooth boles and shining leaves, which always seem to catch and reflect more sunlight than those of any other deciduous tree.

Beyond these come the great variety of Oaks, stretching far along the right of the drive-way, while on the left are groups of Hornbeams, rough-barked and gnarled, some of them with hop-like blossoms and leaves like Elms; and then come Chestnuts in variety, and finally a great mass of Hickories of all sorts, between which and the groups of Butternuts and Black Walnuts the road makes a serpentine curve upon itself, and comes gently rising to the summit of the hill, where, from a circular esplanade, there is an extended view of all the surrounding country, with villages and scattered dwellings nestling amid groups of trees, and the far-away towers and spires of Boston, and in another direction the grand outline of the Blue Hills, the whole making a noble outlook full of variety and beauty such as any park might well rejoice in. Here at your feet lie the groups of Birches, Elms and Ash-trees, with Catalpas on a rising ground behind, by which you pass as you wind round the hill on the east side, coming down to the interesting nursery and the great group of systematically arranged shrubs, two miles and a half of them, if you count the length of the walks between the different beds, where they are grouped in splendid luxuriance; such specimens! so vigorous, so handsome, so laden with blossom or fruit according

to the season! It is enough to make the amateur die with envy to see the way they flourish in the rich soil which is supplied to them, where never a weed is permitted apparently to show its intrusive head.

The vines climb upon tall poles and spread out their branches and tendrils until they resemble trees; the Rose-bushes, all single-flowered, bend over with their weight of blossom. The air is fragrant with Honeysuckles and Sweet-brier. The bees make harvest in the warm sunshine and riot amid the wealth of flowers. You forget you are there to learn something, and revel simply in the great luxuriance of this marvelous garden, where are to be seen specimens from all temperate lands grouped and labeled, so that they become an object-lesson of rare beauty. At whatever time of year you go, these beds are gay with flowers or rich with fruits, hanging singly or in clusters from the bending branches. Do you want a shrub for your garden? Here you can see its effect when brilliant with summer bloom, or jeweled with ruby and amethyst fruitage. Does your porch need the shelter of clambering Rose or twining vine? Here you can judge of the proportions to which it will grow under careful nurture. Do your nursery specimens fail to answer your expectations? At the Arboretum you can learn how to help and stimulate their best development.

It will be hard to tear yourself away from the shrubs, and when you have left them behind you resolutely, there are more trees to see, trees cultivated and trees wild, trees that have been pruned and saved from a lingering death, trees that have been grown from seeds sown in the nurseries of this lovingly tended garden. From Magnolia to conifer they run, in all the varying scale of arborescent beauty; and of all the plantations there are none more delightful than the groups of evergreens growing symmetrically on a slope near the Walter Street entrance.

There is a wonderful charm in these groups of Firs and Spruces in endless variety of form and color—stout little Spruces from the Rocky Mountains, the stately fast-growing Douglas Fir, the beautiful Blue Spruce of Colorado, the Black Spruces from Maine, and the White Spruces from Canada, all flourish here, with many other varieties, which are less interesting, botanically, to me than as the most lovely little trees in the world. For in these plantations, only begun seventeen years ago, every tree is vigorously young. They are raised from seed planted in the nurseries here, and are carefully selected for the vigor and beauty of their growth.

The only thing I complain of is that the Arboretum authorities provide the visitor with no place to sit down and enjoy all these wonderful things, among which one wanders until one is weary with pleasure. One would gladly sit for an hour among these winning evergreens until each had become an identity, making little excursions into the mysterious depths of the bosquets and returning to contemplate some especial favorite. The Pines and Larches are equally lovely, but I have a liking for the sturdy Spruces and Firs, wrapped like Esquimaux in their furry tight-fitting garments, sitting down solidly on the ground, with their pyramidal persistence, bidding defiance to wind and weather, and affording alike shelter and satisfaction.

They tell tales of snowy plains and bleak hillsides and far-away peaks, presenting their serried spears to the blast. Their serrated outline against the sky, familiar to me from childhood, is quite other than that of the deciduous trees of southern New England, interspersed as they are with the broad soft masses of Pine-branches. They have an aspect of their own, full of suggestion to the true northerner who has been sheltered by their somewhat austere presence. They partake, too, of the northern character, really valuable and steadfast but not alluring, full of sharp edges and prickly points, and wearing an aggressive air to strangers, with the same power to kindle and burn with a tremendous flame when the occasion comes.

But do not linger too long among the conifers, for there are natural woods to walk in, that have not been planted, with crackling leaves under foot, and underbrush to catch your garments, and glimpses of blue sky through crowding branches, under whose shade young seedlings spring up strong and tall—a perpetual storehouse of specimens for the Arboretum.

Nor must you go until you have climbed to the top of the Hemlock Hill and rested in the shadow of its mighty giants and learned what centuries can do for trees, and wondered that in the city's heart so fine and wild a tract of woods as this should still exist to gladden the hearts of its inhabitants.

And soon there will be the new museum to see, the splendid gift of Mr. H. H. Hunnewell, with all sorts of treasures within, the great library, and valuable herbarium, which for years

Professor Sargent has been assiduously engaged in collecting, and now generously gives to the Arboretum, with specimens of fruits and flowers, of nuts and cones, of woods and roots, and hundreds of other things that are a delight to the lovers of trees and flowers.

Apart from all there is to rejoice the eye and cultivate the mind in this noble tree-garden, the Arboretum, the thought of its permanence should ever be present with one to fully appreciate how great and valuable and beautiful a gift it is to the

which will then shade its pleasant paths, and be the wonder and delight of other generations. The beauty which we find charming and promising in its immaturity will then be stately and solemn in its perfection of size and venerableness. Far away will be the memory of those who planned this forest for future ages, dim their personality, but unforgotten their names, for these the world "will not willingly let die." In this age, so full of personal struggle, of selfish greed, of individual ambition, it is well to know that men live with small thought of their own fame, who are planning wisely for the future happiness of millions.

Like the roots of the trees they plant, their beneficent mission is hidden from the sight of man, but the outgrowth of their deep-laid plans shall rise in the sight of all the people as a blessing far-reaching and magnificent as the great limbs of the Oaks and Beeches, which shall be their stateliest monument.

Hingham, Mass.

M. C. Robbins.

The Perforation of Flowers.

THE subject of the relations and adaptations which exist between flowers and insects does not appear to excite as much popular attention as many other branches of natural science which are no more interesting. Sprengel, Darwin and Hermann Müller have been the chief authors in giving us our present knowledge and interest in the study; Sir John Lubbock has helped to popularize it, and Professor W. Trelease and others have carried on the work in this country.

The perforation as well as the fertilization of flowers has received attention, but there is a wide field for further study for those who have leisure to pursue it, as it requires much time and patience, as well as closeness and accuracy of observation.

The accompanying figures, from drawings by Mr. C. E. Faxon, show a few characteristic perforations and mutilations, and also represent two of the principal kinds of insect which make them.

Any one interested in the subject will find an excellent brief review of the work already done, a fair bibliography, and a list of perforated flowers, in Professor L. H. Pammel's paper on the "Perforation of Flowers" in the *Transactions of the St. Louis Academy of Science*, vol. v., pp. 246-277.

The general beauty of flowers is usually not greatly marred by the perforations except in a few cases, as when the spurs of Columbines and corollas of Trumpet Creepers are much torn, which frequently happens.

The great object of the perforations by insects is the obtaining of the concealed nectar in an easy way. Very naturally, flowers which depend on insect agency for fertilization rarely produce seed when punctured if they are not also entered in the normal way. Perforating is only practiced by a small number of species of insects, and many, but not all, of the perforators do so because their tongues are too short to reach the nectar by entering the flower. Some obtain nectar from the same kind of flower, both in the normal way and by perforating.

The chief perforators of flowers, in this part of the continent at least, appear to be some kinds of humble-bees (*Bombus*) and carpenter-bees (*Xylocopa*). These insects have developed an unerring instinct as to the proper point to perforate the corollas from the outside, in order to readily get at the nectar. The holes made by the humble-bees and by the carpenter-bees are usually quite different and easily distinguished.

The humble-bees have short, stout, blunt jaws, ill adapted for cutting, and the perforations made by them are apparently always irregular in shape, and have jagged edges. It has been stated that the humble-bees often bore through the tubes of

Fig. 7.—THE PERFORATION OF FLOWERS.

1. *Xylocopa* and heads of male and female. 2. *Bombus* and head. 3. *Dicentra spectabilis*, showing punctures. 4. *Ribes aureum*. 5. *Ligustrum Iboia*. 6. *Aesculus glabra*. 7. *Lonicera involucrata*. 8. *Caragana arborescens*. 9. *Andromeda Japonica*. 10. *Buddleia Japonica*. 11. *Mertensia Virginia*. 12. *Rhododendron arborescens*. 13. *Corydalis bulbosa*.

country. Nowhere else has provision been made for such a garden to exist for a thousand years under practically the same conditions of growth and development, and as one looks forward to the time when these fine young trees shall be mossy with age and decrepit with the wear and tear of centuries, there is great food for the imagination in the thought of the greater Boston that will encompass this wooded region, and of the differing race of men who will walk beneath the overhanging branches of the mighty Oaks and Chestnuts

their corollas with their maxillæ, but in all cases observed by me the mandibles were first brought into use in effecting an opening. The noise caused by the tearing is often audible for a distance of several feet.

The true jaws of the carpenter-bees are not any more prominent or better adapted for making clean-cut perforations than those of the humble-bees; but behind the jaws there is a pair of long, sharp-pointed, knife-like, jointed organs (maxillæ) which seem to be exclusively used on all ordinary occasions in making perforations. The inner edges of these maxillæ are nearly straight, and when brought together they form a sharp-pointed, wedge-shaped, plow-like instrument which makes a clean, narrow, longitudinal slit when it is inserted in the flower and shoved forward. The slits made by it are often not readily seen because the elasticity of the tissues of some flowers causes them to partially close again. When not in use the instrument can be folded back so that it is not conspicuous. The ordinary observer usually sees no difference between the humble-bees and the carpenter-bees, but they may be readily distinguished by a little close observation.

No doubt, in some of the recorded cases of perforations, carpenter-bees have been mistaken for humble-bees. The heads of all our northern humble-bees are rather narrow, retreating from the antennæ toward the sides, and with a more or less dense tuft of hair between the antennæ. The abdomen, as well as the thorax, is always quite densely covered with hair, which may be black or yellowish or in bands of either color. With possibly one or two exceptions, the only species I have seen doing the puncturing is *Bombus affinis*, Cresson.

The carpenter-bees (*Xylocopa Virginica*) of this region have the head very broad and square in front, and with no noticeable hair between the antennæ. The heads of the male and female differ strikingly. In the male the eyes are lighter-colored and are hardly half as far apart as in the female, and the lower part of the face is yellowish white. The female has eyes smaller, darker, and very far apart, and the whole face is perfectly black. The abdomen is broad, of a shining blue-black color, very sparsely covered with black hairs, except on the first large segment nearest the thorax. On this segment they are more dense and of the same tawny color as those on the thorax. But it is particularly from the character of the head that the amateur observer of the perforators may soon learn to distinguish between a *Xylocopa* and a *Bombus* as they work among the flowers. It is also interesting to know that the *Xylocopas* are not so inclined to sting as the humble-bees, and the males, of course, being without stinging organs, may be handled with impunity.

Among other insects, honey-bees have been said to perforate flowers, but authentic instances are rare of their doing much damage, or even making holes. I have only recorded a single instance, and in this a honey-bee was seen to perforate the fragile spurs of *Impatiens*. When searching for nectar they quite commonly use the perforations of other insects. Wasps and other allied insects also perforate for nectar. My only observations being a *Vespa puncturing* *Cassandra calyculata*, an *Andrena* (?) perforating the spurs of *Aquilegia*, and *Adynerus foraminatus* biting holes close to the base on the upper side of *Rhododendron*-flowers. The holes made by some of the wasp-like insects are often more or less circular and with clean-cut edges. The ravages committed by larvæ, beetles and other insects in devouring flowers, or parts of them, do not properly come under the head of perforations.

The question as to the cause of the handsome corollas of the Trumpet Creeper (*Tecoma radicans*) being so often split and torn has been accounted for in various ways in published notes on the subject. Humming-birds and ants have been blamed, the humming-birds being such constant visitors of these flowers that it really seemed as though they must be the authors of the mischief. I have often watched them when they appeared as though they were pecking at the blossoms, but careful examinations, both before and after their visits, always failed to show any trace of injury. Finally, on July 26th, 1890, I was rewarded by seeing a number of Baltimore orioles vigorously pecking at and tearing open a lot of fresh blossoms, and this observation was afterward repeated. That the oriole should do this was not surprising, considering its known habits in relation to some other flowers.

Arnold Arboretum.

J. G. Jack.

[Mr. Jack adds a list of sixteen plants whose flowers he has seen punctured by the carpenter-bee, and seventeen others whose flowers were punctured by the humble-bee. He names more than thirty other flowers which he has found perforated without having seen or identified the authors of the mischief.—Ed.]

Foreign Correspondence.

New Garden-plants of 1891.—I.

A REVIEW of the new plants introduced into cultivation and described in various periodicals for the first time during last year does not reveal much of very decided value. The bulk of them have already been noticed in the pages of *GARDEN AND FOREST*, but, following the practice of previous years, I propose to sweep them all together, marking specially those possessed of horticultural merit. Orchids stand a long way first in point of number. There are exceptionally few new introductions of any note. The hybrids, too, fall short in interest of those of the previous year. Of species, hybrids and wild varieties there are altogether seventy additions. Besides these, there are those Orchids which had previously been rare, but are now abundant in gardens in consequence of large importations made last year. The most noteworthy of these are *Cattleya labiata vera* (Warocqueana) and *Dendrobium Phalænopsis*. *Cattleya Rex* is another recent acquisition of quite exceptional promise.

Ada Lehmanni, Rolfe, differs chiefly in the foliage from the well-known *A. aurantiaca*.

Aërides Laurenciæ, var. *Amesiana*, Sander, is a grand variety of a grand Orchid. It has racemes over two feet long crowded with larger flowers than those of the type (Sander & Co.)

Angræcum fragrans, Spreng., is an interesting little species of economic value in the Island of Bourbon, where its leaves, when dry, are used as tea. (Kew.)

Cattleya Lowryana, Hort., is a pretty hybrid, raised by F. Sander & Co., and described by me in *GARDEN AND FOREST*, iv., 293.

Cirrhopetalum Collettii, Hemsley, is the largest, handsomest and most remarkable species of a remarkable genus. It was discovered in upper Burma by General Collett, and sent by him to Kew, where it flowered for the first time in June last. *C. Wendlandianum*, Kranzlin, is described as a new species which combines the characters of *C. Medusæ* and *C. fimbriatum*. It is not unlike General Collett's plant, and comes from the same country.

Cœlogyne Micholitziana, Kranzlin, is a white-flowered species in the way of *C. speciosa*, which Messrs. Sander & Co. introduced from Macassar.

Cochlioda Noëziana, Rolfe, is a charming little Orchid for the cool house, easy to manage, free-flowering, with elegant racemes of orange-scarlet and yellow flowers. It was introduced in quantity from Peru by Messrs. Linden, Brussels.

Cymbidium pulcherrimum, Hort., Sander, is a beautiful plant, with the habit of *C. Mastersii*, and a dozen or so waxy white flowers striped and flushed with crimson. Messrs. Sander & Co. have introduced it from northern India.

Cypripedium. There are numerous hybrids of this genus, as usual, few being of any real decorative value. The best are *C. Antigone* (from *C. niveum* and *C. Laurencianum*), *C. Berenice* (from *C. Rœbelini* and *C. Lowii*), *C. Ceres* (from *C. hirsutissimum* and *C. Spicerianum*), *C. Castleanum* (from *C. hirsutissimum* and *C. superbians*).

Dendrobium Leeanum, Hort., Sander, is a species from New Guinea, with the habit of *D. superbians*, the flowers being white, mottled with rose and tinged with green (F. Sander & Co.)

Disa Veitchii, Hort., is the best hybrid Orchid of the year. It was raised by Messrs. J. Veitch & Sons from *D. grandiflora* and *D. racemosa*, flowering within two years from the time the seeds were sown. We have made the same cross at Kew, besides other crosses between these and *D. tripetaloides*, and the seeds have germinated freely. It was proved long ago by Dr. Moore, of Glasnevin, that *Disas* could be easily multiplied by means of seeds. I am of opinion that in the three species here named we have very promising material for the production of a really valuable race of easily grown cool Orchids.

Epidendrum Dellense, O'Brien, is a pretty hybrid from *E. xanthinum* and *E. radicans*. It originated in the garden of Baron Schröder.

Habenaria carnea, N. E. Brown, has already been noted and figured in *GARDEN AND FOREST* (vol. iv., p. 475, fig. 76).

Lælia Arnoldiana, Hort., is a handsome hybrid between *L. purpurata* and *Cattleya labiata*, raised by Messrs. Sander & Co. The flowers are as large as those of *L. purpurata*, while the color is that of a richly marked form of the *Cattleya*. There is a good figure of it in *Lindenia*, t. 294. *L. grandis*, var. *tenebrosa*, is a distinct and beautiful variety, the sepals and petals colored a rich terra-cotta, the lip being crimson, with a broad wavy margin of white. It also is represented by a good figure in *Lindenia*, t. 290.

Masdevallia Rolfeana, Kranzlin, is a large-flowered species in the way of *M. velifera*, but colored rich chocolate-brown (Sander & Co.) *M. falcata*, O'Brien, is a hybrid between *M. Lindeni* and *M. Veitchii*, which promises to be a good garden-plant. It was raised by an English amateur, Mr. D. O. Drewett. *M. Mundyana*, Hort., is a hybrid between *M. Veitchii* and *M. ignea*, var. *aurantiaca*, which we owe to the skill of Messrs. F. Sander & Co.

Miltonia vexillaria, var. *Sanderiana*, is a beautiful variety which I recently described in *GARDEN AND FOREST* (vol. iv., p. 545).

Odontoglossum Cookianum, Rolfe, is a supposed natural hybrid between *O. triumphans* and *O. Sanderianum*. *O. dellense*, O'Brien, is another so-called natural hybrid, its supposed parents being *O. Pescatorei* and *O. proenitens*; a third doubtful hybrid is one named *O. Godseffianum*, which is said to suggest *O. Lindleyanum* and *O. triumphans*. It would seem that those who name Orchids are less certain than of yore, if one may judge by the number of introduced plants which are now dubbed natural hybrids. It would simplify matters considerably if such plants were either allowed to rank as distinct species or called varieties of those they are most like. We have a supposed natural hybrid among *Oncidiums* now, namely, *O. Larkinianum*, whose characters are thought to be a mixture of *O. curtum* and *O. Barclayanum*. I should call it simply a bright-colored variety of *O. curtum*.

Peristeria aspersa, Rolfe, was described and figured in *Lindenia*, t. 277. It is in the way of *P. pendula*, the pseudo-bulbs being as large as goose-eggs, and the short pendant raceme crowded with ten flowers, which are almost as large as those of *P. elata*, and colored yellow, thickly speckled with crimson, the lip being blotched with red. It is a fine plant, and was introduced by the Messrs. Linden, from Venezuela.

Phajus maculato-grandifolius, Hort., Veitch, is a hybrid between the two species, indicated in the name. It has the habit of the latter species, tawny, yellow flowers, with a poor lip, a character derived from *P. maculatus*.

Restrepia Imschootiana, Rolfe, is a pretty addition to the genus. It is very similar to *R. Storeyi*.

Restrepia strata, Rolfe, is a charming little Orchid, exactly like *R. elegans*, but with striped instead of spotted sepals. It was introduced from New Granada by Low & Co.

Schomburgkia Sanderiana, Rolfe, is similar to the bull's-horn species, *S. tibicinus*, but with shorter pseudo-bulbs and rosy, carmine flowers. The worst character in the plants of this genus is their shy flowering behavior under cultivation.

Sobralia macrantha, var. *Keinastiana*, Hort., is a white-flowered variety, as already noted in *GARDEN AND FOREST* (vol. iv., p. 305). It is in the collection of Baron Schröder.

Spathoglottis Ericsonii is a yellow-flowered species, which has been introduced by Messrs. F. Sander & Co., but I have not seen it. Possibly it is a form of *S. aurea*.

Stenoglottis longifolia, Hook. f., is a pretty, easily cultivated Orchid, for the cool house. It has been introduced from Natal to Kew, where it flowered this year, the erect scape, eighteen inches high, bearing its pretty, deep mauve flowers for about three months.

Thunia Mastersiana, Kranzlin, is a tall, long-leaved plant, with flowers about half the size of *T. alba*. It has been introduced from Monlmien by Messrs. F. Sander & Co.

Cultural Department.

Seed-sowing.

JANUARY is a dull month as far as garden operations are concerned. The days are so short that growing plants are almost at a standstill, so there is very little potting that can be done; but it is an excellent time to sow small seeds like those of *Begonias* and *Gloxinias*. It is well known that seeds germinate well when kept darkened, and partly owing to this, and because the temperature is under control at this season, small seeds will now germinate evenly and well, and they are not so liable to be washed out by overwatering, because, if they are properly sown, little water is needed until they are above ground.

To destroy all insects and weed-seeds in the soil intended for use it is a good plan to prepare it, sifted, ready for use, and then place it in a tin vessel and bake it for half an hour in a hot oven. This treatment will forestall all trouble with worms or weeds. When sowing a lot of Australian seeds sometime ago I tried the solution of copper, which is said to prevent pots from becoming green, and this, with baked soil, seemed to be a good way to reduce the growth of moss on the soil to a minimum, as perfectly new pots were used. The pots, however, became as green as if they had not been treated with copper, and I am apprehensive, therefore, that we have not yet found a sure remedy for this trouble. Last year from a twelve-inch pan and one packet of seeds we pricked off over 200 *Gloxinias*, about half of which flowered in six-inch pots in July—that is, in about six months from the time of sowing—and there is nothing unusual about this if good seed be used and a temperature of sixty degrees be maintained at night. Many amateurs think that it does not matter much what sort of a night temperature prevails in their greenhouse so long as frost is excluded, and often, too, on a mild night it may be ten or fifteen degrees higher than it was the night before, and then they wonder why tender seeds damp off or never come up. It should be made a point to maintain the right heat from the time the seed is sown, or if this cannot be done in the coldest weather, then no more seed should be sown for another month. In most greenhouses, fortunately, there is a warm corner where a small frame may be placed to put seed-pans in and keep them at a little higher temperature than that of the house itself, just to coax the seed a little at first. After they are up even, and large enough to prick off, lift with a small forked stick and transplant.

As to soil suitable for seeds, there are two cardinal points to be observed. Enough decayed leaf-mold should be added to the loam to prevent it from caking or becoming hard, and enough sand should be added to guard against its becoming sour or water-soaked. Soil of this quality and texture is suitable to receive any seed, large or small. Fertilizers are not desirable in the seed-pans or in the soil used for pricking off into boxes; but when the time comes to pot the young plants a richer soil will be beneficial, for they need nourishing as they gain strength. Such small seeds need very little covering; the pans should be filled to within half an inch of the rim, and a little very fine soil should then be sifted over the surface. If the pans are then well watered and allowed to drain for an hour, the seeds can be sowed evenly and a slight sprinkling of sand should be sifted over them. In watering care should be taken not to wash the sand. A fine sieve suitable for seed-sowing may easily be made with a piece of wire mosquito-netting tacked on to a shallow cigar-box after removing the bottom and the lid. This sieve will be found useful for cleaning seed, especially if wire-netting of different sizes can be procured.

South Lancaster, Mass.

O. O.

Notes from the Harvard Botanic Garden.

APHELANDRA AURANTIACA.—The bright flowers of this plant have a wonderfully enlivening effect in the stove during our dreariest weather. It is a shrub of somewhat dwarf habit, belonging, like many other good winter-flowering plants, to the *Acanthaceæ*. The large opposite ovate leaves, borne on short petioles, are rich dark green on the upper surface, and paler beneath. The flowers are produced in compact terminal spikes from three to six inches long. The corolla consists of a long narrow tube, the greater part of which is hidden by

greenish bracts and a conspicuous, spreading, two-lipped limb, the lower lip being deeply trilobed. The color is vivid orange-scarlet internally, and yellowish outside. The plant is of easy culture, and flowers freely when young. It is readily propagated from moderately firm cuttings with a slight heel of older wood, placed in strong bottom-heat and kept close. The young plants when potted should be placed in a high stove temperature, and have abundant water on roots and leaves while actively growing. A moist atmosphere is essential to hold in check the red spider until the leaves become hard enough to defy its attacks. They may be kept cooler and comparatively dry after flowering, and, like older plants, they should be cut back closely in spring, placed under stove treatment, and repotted when the young shoots have made a fair start. Seeds ripen freely, and seedlings make better plants than those obtained from cuttings. The seeds should be sown when fully ripe, in early spring, and the plants grown on as cuttings are in a stove near the glass. The plant was introduced from Mexico in 1844. The well-known variety, *A. aurantiaca* Roetzlii, was introduced from the same country in 1867. It is a rather better plant than the species, with silvery leaves and brighter flowers.

CESTRUM AURANTIACUM.—This shrub is an old occupant of greenhouses, of free growth and peculiarly graceful habit, and bearing attractive flowers in great profusion. Its dark green,

dom, and is destitute of foliage. The stems are flattened, of lively green color, and jointed in three-inch sections about an inch in width. The bright, rosy purple flowers are some three inches in length, and of bright, rosy purple color. They appear freely at the points of the shoots during the winter and last for several weeks, large plants being often in bloom for months together. A stove temperature and plenty of moisture are required when the plant is making its growth, but after that period the heat may be reduced by ten or fifteen degrees, when water should be applied sparingly and only to the roots. Small portions of the young stems are easily rooted in sandy soil, but the plants obtained by this method of propagation, though useful for hanging-baskets and marginal stage-pots, are not so effective as those secured by grafting on stocks of the Barbadoes Gooseberry, *Pereskia aculeata*. The stock is a plant of the same order as *E. truncatum*, with spiny stems and large, oval leaves. It is easily grown from cuttings to the required height, which varies according to the size of the specimen desired. Neat plants are obtained by using a single cion on stocks twelve or eighteen inches high, and for larger specimens taller stocks must be employed, inserting a cion at the top and others at intervals along the stem. In grafting it is simply necessary to cut away the upper portion of the stock, clean across at the required height; remove a small wedge-shaped piece at the top, and fit a portion of the

Fig. 8.—An Illustration of the use of Herbaceous Plants in connection with buildings.—See page 26.

oval leaves make an admirable setting for the bright orange blossoms, which are tubular and about an inch long, with a small, regularly parted, reflexed limb, and borne in large, loose panicles. Young plants are quickly obtained from cuttings of the soft wood at almost any season of the year. This *Cestrum* should be planted in a sunny part of the garden after the danger of frost is past, and in autumn it should be potted and placed in a cool greenhouse for the winter. In this way it will make a good display out-of-doors in summer, and again under glass in winter. It does equally well in a permanent greenhouse-bed. In any case, older plants should be regularly, though moderately, pruned every spring before vigorous growth begins, but not until the roots have started. Large, full-grown specimens bloom more freely in proportion to their size than those that are smaller, and it is therefore desirable to encourage their development. *C. aurantiacum* is a native of Central America, and was first introduced to European gardens in 1843.

EPIPHYLLUM TRUNCATUM.—None of the Cactus family excels in graceful beauty this little inhabitant of the Organ Mountains of Brazil. It is an old plant in gardens and universally admired, having been introduced about a hundred years ago. The growth has some of the remarkable characters of its curious relatives, but lacks their stiff outline and grotesque aspect. It has a rambling habit, branching with great free-

young stem about three or four inches long with growing tip to the opening thus made, binding it firmly with soft material. Openings made in the side of the stem should be treated in the same manner, and in a few weeks the binding may be removed. Grafted plants thrive most vigorously in a compost of rich loam, thoroughly decomposed cow-manure and sand, but those on their own roots give more satisfaction in a soil something poorer. The former should also be watered occasionally with weak liquid manure, when growing freely, and annually top-dressed with rich soil when repotting is inexpedient. There are many varieties of *E. truncatum*, or hybrids of that species, and the very slightly different *E. Russellianum*. These closely resemble their parents in all but the color of the flowers, which includes selfs of orange, purple, scarlet and pink, and shades of the three latter colors intermixed with white. Under its common name of Crab Cactus this plant is now brightening many a cottage window, and it has few superiors for this purpose among winter-flowering plants.

TOXICOPHLEA SPECTABILIS.—This is the most beautiful plant now flowering in our greenhouses. It is one mass of pure white fragrant flowers and deep verdant foliage. It was introduced from south Africa some twenty years ago, and is one of the most popular of indoor plants. It is of shrubby habit, with opposite, oblong-lanceolate leathery leaves four to five inches long. The Jasmine-like flowers, with narrow tube and

spreading, five-parted limb an inch across, are borne in large axillary clusters, almost hiding the stems and foliage when fully expanded. It thrives luxuriantly in a maximum winter temperature of sixty-five degrees, and may be grown in the open air, either in pots or planted out, during the summer months with entire satisfaction. The flowering season extends through the dullest portion of the year—winter and early spring. The individual flowers do not last longer than a few weeks, but new ones keep opening continually. It is propagated by cuttings of half-ripened wood during the spring months, with a moderate amount of bottom-heat. The plant likes abundant light, and it will not bloom freely nor long retain good health when closely shaded for any considerable period. It is widely known under the name of *Acokanthera spectabilis*, and possesses very poisonous properties. In south Africa it grows in sandy soil convenient to the shore, forming a large bush, and the natives of that region formerly poisoned their arrows with a jelly prepared from its bark.

Cambridge, Mass.

M. Barker.

The Experiment Garden.

ABOUT ten years ago I selected a few beans which had come from apparent crossing; and from that time by selection only, leaving all crossing to natural causes, I began the increase of varieties. The work at first resulted mostly in giving me some very curious and beautiful beans; but the fourth year struck out strains that bid fair to be valuable. In selecting I had in mind (1) to produce wax pods; (2) to secure them free of tendency to rust; (3) to enlarge the yield; (4) to get either white beans, or those that would cook white. There is also a good opening in market for a late Cranberry bean. Bearing such points in mind, I have secured white-podded beans, entirely free of rust, ten inches long, and ten beans to a pod. The yellow field Bean I have turned into a white-podded sort, with no change in the bean. It was easy to cross in the southern Cow Pea, but no special advantages have occurred from it. The result is a small wax pod, growing on vines that may be trellised like peas. It was difficult to secure crosses of the Lima, and those that I have so far secured are not of high value. The Lima may improve other Beans; it is not likely to be improved by them. But by selection I am in possession of a strain producing generally five beans to a pod, and occasionally six. By careful breeding I believe a six-beaned pod can be fixed, or even better.

In working out rust, I found that the Golden Wax was the worst possible parent. Nor am I sure that any sort from that crossing is quite sure of being spotless in bad seasons. Crosses of the Horticultural or Cranberry are peculiarly unstable, as are also those of the old Refugee. But I have been able to fix a few of considerable promise. From first to last I suppose I have obtained at least five hundred new crosses of Beans. Of these I have retained about one hundred. Each year shows some strain of value; but I am now intent only on suppressing the tendency of broken-up varieties to cross into new sorts.

One experiment only in Raspberries has given me a strain of very early sorts, some varying toward the Philadelphia, and others toward the Cuthbert, which were the parents. These give hope of securing at last an early berry as good as Cuthbert is for main crop. At least I have no results so good from any of the old sorts as from these. They need further testing, as I have so far only given them a crowded chance in my experimental plot.

Exactly what I have in the way of Grapes to offer I cannot determine; but returning to my home about October 1st, last year, I found there sorts already dried on my vines in a row of neglected seedlings. They were, as half raisins, delicious, and must have been very early. One was red, one white and one black. Small seeds, medium clusters and medium berries were the characteristics.

The experimental garden is the most interesting side of fruit-culture and farming in general. It does not often prove profitable, but we are able to contribute somewhat to the store of knowledge, and possibly may add to the list of human foods. These are but few of many attempts at improving fruits, vegetables and flowers, and, although I have reached no striking results, I consider the time and labor well repaid in the way of self-culture.

Clinton, N. Y.

E. P. Powell.

Autumn Snowdrops.—My experience with these plants has been very limited, but I am an anxious inquirer on the subject, and the note of Herr Max Leichtlin was even more interesting than many of the always valuable communications from Baden-Baden. In studying up the Snowdrops I have never been able to determine from the writings of the experts

the actual difference between the early-flowering forms—*Galanthus Olgae*, *G. nivalis* *Octobrensis*, *G. nivalis* *Corcyrensis* and *G. Rachelæ*. If I understand the matter rightly the two former bloom at the same season, and by some persons they have been considered identical. Snowdrops, like most plants, vary in size of flowers and in time of blooming, according to location and culture, and in the open, conditions of temperature, of course, will have their effect. In view of this it seems difficult to separate the variety *Octobrensis* from *Corcyrensis* with the present data. Herr Leichtlin says the segments of *G. Octobrensis* are a little narrower than those of *G. Corcyrensis*, yet I understand that he has raised some seedlings of the latter variety which have very narrow petals and which bloom a month earlier than the parent. It would be interesting to know how these latter compare with *G. Octobrensis*. Here we have a point where, if anywhere, the difference of the varieties could be determined and described. In a collection of Snowdrops secured by me last summer the varieties *Octobrensis* and *Corcyrensis* were said to have been included, and I was rewarded early in November with flowers of what I determined to be *G. Octobrensis*. Later I have been favored with a succession of blooms of what I suppose is *G. Corcyrensis*. These are nearly over, and have lately disappeared in a snow-bank, but to-day I picked a still perfect flower, and I find them of much superior form to some typical flowers just received from an English amateur friend. The segments are seven-eighths of an inch long by three-eighths broad, the ovaries very small and of a pale green, the inner segments white, with green markings and deeply notched. As Snowdrops usually improve after being well established, it is fair to assume that another season will see them in even better form. Whatever the varieties prove to be, I have a promise of Snowdrops from October till *G. Elwesi*, which is now showing color, is prepared to carry forward the succession.

Tomatoes.—Ten weeks before the date when it is safe to set the plants out-of-doors, in any given locality, seeds of early Tomatoes should be sown in boxes in a warm greenhouse or in a sunny window. As soon as the little plants are fairly under way and before they get drawn, they should be transplanted into another set of boxes about two inches apart, or potted into three-inch pots. The latter plan is best when there is room. Four weeks before it is safe to finally place them in the open ground, they should be transplanted into a cold frame four inches apart each way, and gradually inured to the air. When carefully hardened, they should go outside as soon as it is safe for them; a light hoar-frost will do them little damage, and they had better be outside to start with the first warm weather. In a recent bulletin from the Cornell Station Professor Bailey mentions the advantage of early setting, and this is a point to be insisted on. I have had large stout plants, that had been gradually inured to the outer air, white with hoar-frost after going out, without suffering serious injury. The plants turn purple with the cold and stand still apparently for a while, but really they are getting a firm hold in the soil, and as soon as the weather warms up they are ready at once to do their best. I have in this way had plants, set out May 1st, in northern Maryland, give me an abundance of ripe fruit on the 20th of June, while some of the same lot of plants, kept back a week later in the frames as an insurance against loss of the first, did not give fruit until July 10th. Here, plants set out April 1st and exposed to slight frost, gave ripe fruit May 25th; and part of the same lot of plants, set out in middle of May, gave no ripe fruit until June 15th. While it is usually a great advantage to get the plants out at the earliest practicable moment, there is, of course, some risk connected with it, for the frost may come too severely. I therefore always take this risk only with part of my early plants, reserving the remainder to insure against entire failure should the first be killed.

Early Cabbages.—We are now (January 8th) transplanting our early Cabbage-plants (from seed some only ten days ago) into boxes, preparatory to putting them out in the cold frames. We prefer this practice to sowing the seed in the fall and wintering the plants over. While Cabbage-plants in this latitude stand outside without any trouble, it is hard to select the best time for sowing the seed in fall, as warm weather sometimes persists so late that the plants get overgrown, and then run to seed in spring instead of heading. These plants we are now pricking out into boxes will be ready to go into the open ground the latter half of February or earlier, and will be but little if any later than the fall-set plants, while none of them will run to seed. This practice is just as good northward as here, only the sowing should be deferred, in the lati-

tude of New York, until February, and the plants hardened off so as to go out late in March. In either place it gives a chance to use the sashes on the cold frames before the Tomato-plants need them, as the Cabbage-plants can go outside just at the time the Tomato-plants should be ready to go into the frames. The frames we are now putting the Cabbage-plants in have just been cleared of Lettuce, and will have constant use from now to April.

The Forest.

The Forestry Movement in the United States.

THIS was the title of a paper read before the late Forestry Convention in Washington by Mr. J. D. W. French, of Boston, Massachusetts. It was an exhaustive résumé of the direct efforts that have been made in this country for preserving our forests, and it was accompanied by a chronological list of the more important events in the history of the movement, such as the acts of Congress and state legislatures, the founding of various organizations, the publication of books and other literature bearing upon the subject. This last compilation, which Mr. French calls *Forestry Annals*, begins as early as 1681 with the ordinance of William Penn demanding "the reservation of one acre of trees to every five acres that were cleared," and gives a very complete record of the various occurrences, according to their dates, up to the present time. Our space will not admit the publication in full of these papers, and we can only touch upon the subjects treated. The complete record is, however, a valuable one, and will be of great use to the future historian of our forests. Mr. French first gave a graphic picture of the present condition of our woods, and began by quoting the language of an official of the state of Arkansas, who, when asked as to the state's policy regarding its timber, sent back the reply, "To get rid of the timber." If deeds speak louder than words, this has been the policy of all the states in the Union, and the priceless heritage which the Almighty planted in abundance throughout the land seems hastening, with the Indian and the buffalo, to destruction.

In speaking of the movement for preserving our forests, Mr. French said, "As early as the year 1817 an act was passed reserving lands producing Live Oaks and Red Cedars to supply timber for the navy. In 1831 another act was passed which included other timber, and imposed penalties for its violation. 'Upon this old law,' says Mr. Bowers, the Secretary of the American Forestry Association, 'having the construction of a wooden navy in view, the Government of the United States has to-day chiefly to rely in protecting its timber throughout the arid regions of the west, where none of the naval timber, which the law had in contemplation, is to be found. Can it be wondered that this act does not meet present conditions?' With all our boasted progress as a nation, we are dependent upon such an antiquated and inadequate law for the protection of our timber."

Other laws alluded to were several allowing the cutting of timber and the purchase of forest-lands, the so-called Timber Culture Act, repealed by the last Congress, and the section authorizing the President to establish reservations, of which we have several times spoken at length. The only action taken by an individual state to secure forest-reservation within its borders is that by New York, and yet the proposed Adirondack Park lacks the necessary legislation to become a realized fact.

The first attempt on the part of Congress to collect definite information in the interest of a systematic forest-policy was made in 1876, under which Dr. Franklin Hough was appointed by the Commissioner of Agriculture to make a report. This report remains a very useful book of reference, and others were afterward prepared by Mr. Hough. The Forestry Division of the Department of Agriculture was organized in 1881, and it remained under the charge of Mr. Hough for two years, when he was succeeded by Mr. N. H. Egleston. In 1886 this Division was made an organic part of the Department, and Mr. B. E. Fernow became the Chief of the Division, with whose efficient labors in various directions our readers have been kept informed.

The American Forestry Association was organized by Dr. John A. Warder in 1875, and since 1882, when the session was held in Cincinnati, there have been yearly meetings. This Association has done much valuable work in arousing public interest, in promoting the formation of local associations and in urging measures of desirable legislation by publishing from time to time its proceedings, and in other ways diffusing

useful knowledge on the subject of forestry. Notwithstanding the apathy of the public and the neglect of Congress this Association has steadfastly trusted that the good sense of the American people will finally bring them to realize the importance of this work and to compel legislative action in the lines which they have indicated.

The work of various other societies is next summarized, and honorable mention is made of the individuals who have not only done practical work in the way of tree-planting, but who have been instrumental in creating a proper public sentiment.

Under the head of "Literature" Mr. French gives a brief account of the books published by Michaux, Nuttall, Emerson, Sargent and others, and a notice of periodicals like *Forest Leaves* and *GARDEN AND FOREST*. The establishment of the Arnold Arboretum in 1872 is noted as an important advance in furnishing object-lessons in every branch of forest-science, and the Missouri Botanical Garden is described as another agency which may be of great value in the same direction.

Mr. French considers the reservation of forest-lands without laws for their care and protection about as absurd as it would be to build a mill and then fail to supply it with machinery. "It is true, however," continued Mr. French, "that the Secretary of War, in answer to a request made by the Secretary of the Interior, has sent squads of cavalry to guard some of the parks, as the Yellowstone, the Sequoia and the Yosemite. Under the present condition of our laws there can be no better plan than to employ our army as forest-guardians. The army is eminently fitted to become custodians of our forests, and, moreover, it can be called into service immediately without going through the tedious process of passing laws. Now, if a knowledge of forestry could be added to its other desirable and available qualities, and proper laws of administration should be adopted, the problem of the care and preservation of our forests would seem to be in a fair way of solution. Why might there not be a Chair of Forestry at West Point, and a Forestry School to teach the soldiers practical forestry on one of the western reservations? Could any better use be made of a portion of the army in time of peace than to instruct it in the principles of forestry? Would not a better class of men volunteer, and would there not be fewer desertions, if forestry and other subjects of importance were taught at some of the army posts? An army post might, under these circumstances, become a school at which a soldier could learn something more than mere military routine.

"With instruction in forestry at West Point there would in a few years be a number of men competent to teach. England has been compelled, from the difficulty of obtaining properly trained men for the Indian forest-service, to establish a forestry school in connection with the Royal Indian Engineering College at Cooper's Hill. It might be a wise thing for our Government to send a few capable young men to Europe to study forestry, with the understanding that they should return to give a certain number of years to Government service. No matter what the laws are, there can be no proper forest-administration until we have men in charge who have at least some knowledge of forestry.

"The most important thing, however, at the present time, is to save the forests on the public domain at all hazards from fires and thieves, and this can be done under present laws only by the use of the army. The army, as it now exists, is quite capable of carrying out what is called the 'common-sense management,' which consists, according to Mr. Fernow, in avoiding unnecessary waste, in protecting against fire, in keeping out cattle where young growth is to be fostered, and in not preventing, by malpractice, the natural reforestation. One of the bills prepared by the American Forestry Association, and known as the Dunnell bill, authorized the employment of the army as custodians of the public forests.

"Legislation is certainly needed, and this can only be brought about by persistent agitation. This important subject should be urged upon public attention at home, on the rostrum and in the newspapers. Drill it into your Congressmen with the keen-edged sword of your votes. In this way, and in this way only, can we hope to influence public opinion."

Correspondence.

Eckford's Sweet Peas.

To the Editor of GARDEN AND FOREST:

Sir,—The fact that thirteen out of the thirty new Sweet Peas of Henry Eckford have received first-class certificates from the Royal Horticultural Society of England, gives him the pre-eminent place as a hybridizer of this flower, and therefore

some extracts from a letter recently received from him may be of interest to the lovers of this flower:

"I first took up the Sweet Pea about fifteen years ago, collecting six of the most distinct varieties I could find, carefully fertilizing the one with the other, year after year selecting the most promising for recrossing, keeping in view properties most desirable to develop—that is, color, form, substance and size. At first progress was slow, but after seven or eight years' patient working, the varieties, some of whose praises you have so well sung—Orange Prince, etc.—made their appearance. When I first began working with the Sweet Pea, experts in the art, as far as I could learn, had come to the conclusion that it could not be further improved, and in the first two or three generations of the work this appeared a fair conclusion. But I had been for many years working on the improvement of various florist flowers which had proved eminently successful, and a first rebuff did not deter me from further attempts. With some of the results you are acquainted, and there are others which, of course, can only be presented to the public as I can get stock of them. It is a great satisfaction to know from all parts of the world that the public appreciate my gems."

Mr. Eckford's Sweet Peas have striking merit, and especially the expansion of the Standard is making an essentially new flower. The new varieties for 1892 show a still nearer approach to lemon-yellow.

Japanese Art in the Arrangement of Flowers.—II.

In the earlier styles of the art of flower-arrangement, Mr. Conder tells us, the use of many different flowers in one composition was allowed. But this is opposed to the principles of the purer styles afterward developed. "Combinations of two or three different species are, however, very common, and especially applied to vessels having two or three openings. In all compositions, single or combined, the special nature of the different materials employed is in each case carefully kept in mind, and anything at all suggestive of the inappropriate must be scrupulously avoided." We have already noted some of the principles which govern these combinations; "but," says Mr. Conder, "important distinctions are made between trees and plants, and between land and water plants. The locality of production, whether mountain, moor or river, considerably influences the arrangement adopted. . . . In arranging two or more species in one composition variety must be secured by combining trees and plants. In the case of three lines being used, the branches of a tree should never be supported on both sides by a herbaceous plant, nor should an herb be placed in the centre with a tree-arrangement on either side. This fault is called by a term which will be better understood if freely translated as 'sandwiching.' In a triple arrangement it is plain that two branches of the same kind of growth must be used, but these must adjoin and not sandwich the remaining one. As an example of a defective arrangement may be taken a composition with Irises (herbaceous) in the centre and branches of Azalea and Camellia (trees) on either side. A correct composition would be one with a Plum-branch in the centre with a Pine-branch on one side and a Bamboo-stem on the other. . . . Herbaceous plants are regarded as female with respect to trees, which are considered male because the former are weaker and more graceful in character than the latter. A slender herb flanked on either side by tree-branches would give a weakness of effect to the centre composition, and the reverse arrangement would give too much strength to the centre and weakness to the sides. In addition to this, such arrangements would have a more or less symmetrical character, and symmetry is disliked throughout the whole of the art under consideration. Like most arbitrary rules, such directions were often departed from by the more advanced professors, and there are even recognized exceptions which are universally admitted as correct. For example, two kinds of Pine-branches may be used together with the Plum-branch in a double arrangement. . . . The branches and foliage of evergreens, and even of deciduous trees, are much used in floral compositions, the arrangement often being without a single blossom. It is, however, laid down as a general rule that no flower-bearing plant is to be employed with leaves only. Nor must plants or trees which bear leaves at blossom-time be used with flowers alone. The following are exceptions to this rule: the large-leaved Chinese Orchid has a flower, but it is very insignificant and grows below; and this plant is, therefore, technically treated as a flowerless one. The Iris Japonica is sometimes arranged for its

leaves only, before the flowers appear, and it then receives a special name. The leaves of the Summer Narcissus are faded and withered before the flowers appear, and they may therefore be removed and discarded. All flower-compositions must partake as much as possible of the spirit of the season in which they are used. Spring arrangements should be straight and powerful in line, like the growth of early vegetation; summer arrangements must be full and spreading; while those of autumn should be spare and lean, and those of winter withered and dreary."

Here again we see how diametrically opposed to western ideas are the ideas of the Japanese. To us flowers are most beautiful and most precious, as a rule, when most conspicuously out of season; and it is safe to say that a vase full of Roses in midwinter gives the average American or European more delight than it would in midsummer. To us the sentiment of a flower merely seems increased by the unexpectedness of its appearance, and one which in winter carries us back to the sun and breezes of June would never be objected to on the score of inappropriateness. In truth, we have no conception of what the Japanese mean by appropriateness, either in this or in any other art; and when we try to understand their point of view, it sometimes seems as though so many recondite, philosophical and emblematical considerations preface their enjoyment of the works of nature that this enjoyment cannot be as fresh and spontaneous as it is with us. But such ideas are, of course, quite mistaken. It is a question whether we shall ever rise to such a many-sided, delicately developed love for the works of nature as the Japanese possess; but we may be sure that every added meaning they read into their flower-arrangements increases, not lessens, the pleasure they confer; and that every added degree of keenness and fineness in æsthetic perception has the same effect.

Of course, color as well as form is considered by the Japanese in their flower-arrangements, and also the shape and character of the leaves, no less than the direction of the stems which bear them. Moreover, the flower-vase is almost as important as its contents, and the relationship of the two is a special and complicated subject of study. There are V-shaped vessels and broad ones, vessels for water-plants, flower-baskets and Bamboo vases, hooked vessels, suspended vessels, flower-chariots, and so on, and in each of these classes there are many varieties, and the choice of each is dictated by the special character of the plants employed or the special effect desired in their combination. To secure plants in the exact positions desired, from which a hair-breadth of deviation would seem calamitous to a delicate eye, special flower-fasteners are required, and these are often made of bronze and given ornamental shapes appropriate to different kinds of plants. Flower-trays and stands must also be carefully considered, as the effect of a beautiful arrangement placed in an appropriate vase might be ruined if it were set on an inappropriate support. Mr. Conder gives many pages of cuts showing flower-vases and stands with and without flowers. Their variety and the subtle distinctions the Japanese draw between them may confuse the occidental mind to such an extent that it will seem, indeed, as though years of patient study would be needed before one should dare to introduce a flower as decoration in a room. Yet even this is not the end of the study of the Japanese. The position of flowers in rooms is another vital point of consideration, and one to which Mr. Conder devotes a special chapter. Then he gives a long chapter to the ceremonial uses of flowers and their significance in the elaborate etiquette of the people. What, one wonders, would the guest in an American house think if, as a special compliment, he were invited to make an extemporary arrangement of flowers, being presented for the purpose with certain suitable flower-stems or blossom-clad branches and all the necessary utensils and implements? Special flowers are named for betrothals, for wedding festivities, for coming-of-age celebrations, for promotions in rank, for the ceremony of religious retirement, for old-age celebrations, for farewell gatherings, for presentation to the sick, for death anniversaries, for house-warmings, for duty ceremonials, for poetry meetings, for incense meetings, for placing before household shrines, for use when rain or fine weather is prayed for, and for that favorite pastime of the Japanese which they call moon-viewing. Nothing could better explain the delicacy of the Japanese artistic sense than Mr. Conder's little description of this last-named ceremony and its floral accompaniment. "The more important dwellings," he says, "have a special chamber with open galleries, from which the sight of the moon-lit landscape can be enjoyed. The floral arrangement occupies the recess of the chamber, and has, of course, no real connection with the outside prospect, but in the flower-composition itself the idea of the moon-lit

landscape is expressed. A branch of a Pine-tree is used, and between the principal and secondary lines of the composition a special branch is introduced, fancifully called the moon-shadow branch; a gap is also formed between the foliage, bounded by the special branch called the dividing-branch. In the composition the idea is to suggest both the opening through which the moon can be partially observed, and the dark branch which appears to cross its surface. To fully appreciate the analogy one must be familiar with the scenery of Japan, and have seen the irregular Pine-trees standing out against the starry heavens."

The concluding portion of Mr. Conder's book is filled with practical examples. Many plates illustrate arrangements of more or less complexity, and each is carefully explained and the reason of its beauty pointed out. As we look through these pictures we are more and more impressed with the fact that, to a Japanese, our own methods of flower-arrangement must indeed seem crude, barbarous and confused. It is impossible to imagine western people having the patience to develop an art of flower-arrangement so elaborate and suggestive as that of the Japanese; nor is our mental temper such that we could ever care, as they do, for recondite, philosophical, historical rules and sentimental meanings to be expressed by flower-compositions. Nevertheless, the artistic aim of the Japanese artist is never subordinated to any other, and a very keen feeling for beauty really underlies most of the distinctions which he explains in ways which to us seem fancifully intellectual rather than æsthetic. It is a pity, therefore, that Mr. Conder's book should be so large and costly that we cannot expect it to have much direct influence upon public tastes in this country and in England. But many of its lessons will certainly be popularized in the pages of horticultural papers. We wish that his illustrations might be largely reproduced, for, of course, pictures are needed to point the meaning of his words; but, unfortunately, his title-page bears the legend "All rights reserved," which, we presume, makes it impossible to copy his cuts without special permission.

There has here been no attempt, we repeat, really to review his book, which is an admirable monument to his own industry and intelligence, as well as to the artistic qualities of the Japanese. The value of such a work depends upon each of the details it explains and upon their full and orderly exposition. All we have attempted to do is to show by a few quotations how interesting and novel it is, and to recommend its careful perusal by any one who may be fortunate enough to find a copy at hand.

Notes.

We learn from a Washington dispatch that President Harrison has issued a proclamation reserving from entry the Pecos River tract, in New Mexico, which is alluded to in another page of this issue.

In Japan the Pæony is cultivated in long sheltered beds, generally lying beneath one of the chief rooms in the house, from which its splendid blossoms can be surveyed. It is the favorite flower of the upper classes, and, being cultivated to produce enormous flowers, often bears blossoms nine inches or more in diameter.

When too little water is given to house-plants the wilted and drooping leaves soon indicate what the trouble is, and it is very easy to apply the remedy before any serious injury is done. When too much water is given, however, the injury is not discovered until perhaps the leaves turn yellow and begin to fall, and it is then sometimes too late to repair the damage. This means that it is easier to injure house-plants beyond remedy by giving too much water than by giving too little.

Monsieur Henry Lévêque de Vilmorin has been elected First Vice-President of La Société Nationale d'Horticulture de France in place of the late Auguste Hardy. This is the most important horticultural office in France, as the President of the society, usually some distinguished statesman, is merely a figure-head, the real administration of the affairs of the society devolving on the First Vice-President. The society is to be congratulated in being able to place itself under the direction of one of the best-equipped and most famous horticulturists of his day, and the worthy representative of a family which has been distinguished for generations for its scientific attainments, its commercial enterprise and integrity, and its zeal in worthy effort to ameliorate every rural art and science.

According to Professor Massey the central Oak-belt of North Carolina is peculiarly the home of the Peach, just as the mountain region is of the Apple. This is especially true of the up-

land sandy ridges which rise some five hundred or six hundred feet above the sea, and which, while in the geographical limits of the Oak-belt, are really Pine-lands. Professor Emery, of the North Carolina Experiment Station, while rambling last year through the forest near a health-resort known as Southern Pines, came across what had once been a Peach-orchard, but which had grown up with Pines twenty or thirty years old. Yet here among these conifers were a number of the old Peach-trees, with trunks measuring nearly a foot in diameter and full of fruit. Most of the trees had been blown over, but even these had put out new heads, which were full of fruit. In Davis County, between the forks of the Yadkin River, wild Peach-trees are abundant along the fence-rows and in old sedge-fields, and these bear large crops with no cultivation or care.

In an article on Christmas supplies in the *Journal of Horticulture*, London, it is said that one of the most striking features in the markets is afforded by the numerous auction sales of imported fruit, and is a matter of surprise how such quantities can be disposed of, and what becomes of home-grown fruits. Thousands of baskets of American apples have been received and sold within the past few days, bright, even, well-selected and well-packed fruits, which would command purchasers anywhere, the Newtown Pippins and Baldwins being the favorites. Side by side with the American apples were bushels of English apples, and the contrast was almost painful. These last were irregular, unselected fruits, seemingly shot into baskets without heed and care, handsome fruits and rubbish intermingled, with the result of a very low average. This is one great defect of English growers, and however the cultivation of fruit may be improved, it will never produce the proper results until the cognate matters of packing and displaying receive due attention.

Mr. Romeyn S. Hough writes us that in a copy of Evelyn's *Silva*, which bears the date of 1664, is a marginal note which was penned perhaps a century ago by some former owner of the book whose name is lost. As it relates to American trees and forcibly illustrates the value of tree-planting, it will doubtless interest our readers: "The false Acacia in North America (*Robinia Pseudo Acacia*, Linn.), vid. Monthly Review for April, 1788, *Memoirs of Agriculture* published by the Royal Society of Agriculture at Paris; *Memoir* 9, by Monsieur Saint Jean de Crève Cœur. A farmer on Long Island planted in the year of his marriage an old worn-out field of fourteen acres with this Acacia, resolving not to touch it till his first child should be of age to marry. His eldest son, when twenty-two years old, anxious to settle by himself, applied for assistance to his father, who then sold out of this wood (to a ship-master) timber to the value of 6,250 French livres, about £260 sterling, which he gave to his son to purchase a plantation in the County of Lancaster. Three years afterward he sold as much as brought the same sum, with which he apporportioned a daughter. In fine, without any other resources than the sale of wood from these fourteen acres, planted in the year of his marriage, he has provided for all his family, and the wood continues to be still equally productive."

The January number of the *American Agriculturist* celebrates the semi-centennial anniversary of its establishment by a series of articles on the great progress which has been made during the last fifty years in agricultural science and practice in America. Interesting articles for this number have been prepared by experts to show the improvement in agricultural machinery and methods of cultivation, in the breeds of domestic animals and poultry and in the different varieties of grains, fruits, vegetables and flowering-plants. There are articles, too, on such comparatively new industries as the export trade in beef, the production of beet-sugar and the growing of vegetables under glass. Dr. Riley writes of the important position which applied entomology now holds in agricultural practice; Dr. Halstead of the new methods of treating fungous diseases of plants, and Dr. Jenkins of fertilizers and their increased use, while Mr. Berckmans discusses the development of pomology, and Mr. Ellwanger records the growth of the nursery industry. Altogether the present condition of American agriculture, when compared with what it was fifty years ago, warrants Mr. C. Wood Davis' prophecy of a brilliant future. This issue of the *Agriculturist* also contains portraits of all its editors, beginning with Mr. A. B. Allen, who still lives at the age of ninety years, and was able to contribute an article to the jubilee number of the magazine which he founded in 1842. Our readers will unite with us in wishing a long continuance of prosperous life to the magazine under the efficient conduct of Dr. Hexamer, who now guides its policy.

The Beauty of Evergreens in Snow.

ONE of the loveliest of all winter effects is seen when wet and clinging snow falls upon the green branches of conifers, emphasizing their beautiful outlines by its "ridge of pearl."

The peculiar delicacy of snow-shadows, with their tender bluish tint, has something to do with the charm of such a scene as is depicted on page 41, and black and white, however subtly shaded, cannot convey that combination of color peculiar to a winter landscape, that fills the eye with a sense of beauty whose evanescence adds to its precious quality.

The sheeted ground sparkles in sunshine with myriad lights; its seemingly unbroken surface, if studied, reveals innumerable soft dimplings, where lurk the shadows that diversify its whiteness. Through the mass penetrate here and there the brown spears of plants and tall grasses, their dry leaves and shrunken blades tipped with silver, their faded blossoms feathery with plumes of snow. Small trees, springing in the shelter of their elders, are overwhelmed with an ermine burden, beneath which they bend like a boy-prince weighed down by a regal mantle too heavy for his youthful shoulders, and their broken shadows fall upon the snow in wavering patches of purple and gray. Where the drifted snow has been melted by an underlying hillock, its dash of yellow-brown gleams like a golden boss upon a silver shield.

The tiny tracks of woodland creatures, which have stolen forth for provender, make interesting suggestions of hidden life in the solitude, guiding the traveler into the shelter of the trees, where in the crotches of the branches the snow lies massed in great heaps. Each bough shows its outline doubled by a furry trimming. The tall trunks are flecked with snowy patches. If the tree be deciduous a reproduction of its line, firm and graceful as a Japanese drawing, lies across the white ground. Here at your feet, like a master's sketch, can be seen emphasized the swelling of

the limb as it throws out a bough, the delicate interlacing of branches, the intricate network of the topmost tangle of twigs. The pyramidal form of the evergreen flecked with light is tenderly reproduced in a tint hovering between blue and gray, which is the despair of the painter, as it is the delight of his eye.

Near the base of the trees where the ground is sheltered, the snow has been warded off, and the soft brown carpet nestles warmly up to the roots and stems, while the wide branches curve with their tips in the snow, making an arched wigwam, protected from the storm. The top needles, agitated by a morning zephyr, have shaken off their hoary hoods, and stand up green and shining against the pale blue of a winter sky, innocent of cloud. As the sun climbs higher there is a low patter among the branches, a fall of snow from an upper limb; soon the rebound of a released branch brings on an avalanche, as the sturdy tree struggles to shake itself free from the encumbering mass. Then from the tree distils an aromatic fragrance as the wet branches grow warm with the approach of noon. The stir of the branches, the rustle of the melting snow falling among them, give a low sweet murmur, the song of the young Fir-tree dreaming of the far-off Palm; of the old Hemlock sighing for some Indian dryad of its youth; of the Pine whispering a saga of a sea-fight and a storm.

The effect of looking down a woodland-path when the trees on either side are laden with snow is of some strange massive architecture of marble, through which one wanders, wondering at the freaks of the builder who has planned these bewildering arches and groinings, supported on columns of diverse proportions. Fantastic forms are everywhere apparent, and the stillness is that of a deserted cavern furnished with stalagmites that ape a forest. For Nature in her various processes is at one, whether she builds trees of stone, or stiffens her forests into a mammoth cave of wonders; and to see these underground effects beneath a blue sky is one of the shows of winter, which has its own museum of delights, wherein ice and frost and snow play marvelous and varied rôles for the beholder.

Dr. Mayr on the Parasitic Fungi of North American Forest-trees.

IN GARDEN AND FOREST, of December 24th, 1890, appeared a review of Dr. H. Mayr's *Die Waldungen von Nordamerika*, in which the reviewer criticised that portion of the work relating to the fungi found on forest-trees. Since the appearance of the review Dr. Mayr has kindly sent to the editor of GARDEN AND FOREST specimens of some of the fungi mentioned in his work, with the request that they be submitted to the reviewer and the result of his examination printed in GARDEN AND FOREST. The following notes are therefore offered in compliance with Dr. Mayr's request:

In our former notice we expressed the opinion that what was considered by Dr. Mayr to be a new species, and called *Rhytisma punctiforme*, was in reality the *R. punctatum* described by Fries in 1819, founded on the *Xyloma* of Persoon, 1801, a species found both in Europe and North America, where it is common, having been recorded in this country in 1831 by Schweinitz. An examination of Dr. Mayr's specimen of *R. punctiforme* shows that it is undoubtedly *R. punctatum*, Fries, which is considered by Rehm and some other recent writers to be a good species, although it was regarded by Tulasne as a form of *R. acerinum*. In our review it was also remarked that, as far as could be told from Dr. Mayr's description and figures of his *Microsphaera Corni*, it was identical with the *M. pulchra*, Cooke and Peck, described in 1872. Examination of the specimens sent confirm the accuracy of our former statement, the appendages, asci and spores agreeing entirely with those of *M. pulchra*, and whether one agrees with those mycologists who believe that *M. pulchra* should be referred to a still older species or not, if the spe-

cies be regarded as distinct, there is no doubt that the name *M. pulchra* should be adopted.

We have examined carefully the specimens of *Lophodermium infectans* and *Hysteriopsis acicola*, and in both cases found only young perithecia, without any trace of spores, in the absence of which it is impossible to say to what genus they belong, still less to what species. Dr. Mayr states that he did not find mature stages, and that being the case, we do not think that he was warranted in saying anything more than that the two immature forms in question belonged to some indeterminable species of the order Hysteriaceæ. We are unable to understand the reasons given for making the new genus *Hysteriopsis*. On page 340 it is said "the genus (*Hysteriopsis*) differs from those existing in Europe, all of which live on young shoots (*Triebbewohner*)." But only a few lines previously he says that "the needles of *Picea Sitchensis* become diseased as if under the influence of a *Lophodermium macrosporium*." Now, since *L. macrosporium* attacks the needles (see Hartig, *Wichtige Krankheiten der Waldbäume*, pl. vi., fig. 1-4) it is difficult to see why it is necessary to separate *Hysteriopsis* from *Lophodermium* because it grows upon the leaves. In fact, the admitted resemblance to *L. macrosporium*, which certainly does attack the needles, makes it probable that, if *Hysteriopsis acicola* be not really an American form of *L. macrosporium*, it is, at least, a nearly related *Lophodermium*, which, in the absence of sufficiently well-developed material, cannot be determined.

The specimen of *Puccinia Abietis* on *Abies concolor* we were particularly glad to be able to examine because the original description differs so much from that of any of the *Uredineæ* known to us that we were unable to recognize the fungus as a species of that order. Dr. Mayr considers that there is at first an æcidium, and that there later develops in and near the æcidia a mass of uredospores, from which, at length, develop teleutospores. The accompanying figures, however, bear little resemblance to any uredo or teleutospores known to us. An examination of the specimens themselves shows the æcidia with their peridia, spores and spermogonia. It is unnecessary to consider what the name of the æcidium is, because, owing to the fact that the specimens are too old, what we might say on this point would be of the nature of a conjecture rather than an exact determination. The important fact revealed by our examination is that what is called by Dr. Mayr the uredospores is in reality not a uredo at all, but a species of *Tuberculina*, a genus well known to infest *Uredineæ* in their different stages. Whether, in the present case, we have before us the common *T. persicina*, or some closely allied *Tuberculina*, can hardly be definitely settled since the material is too old. If the æcidium has evidently been attacked by a parasitic *Tuberculina*, the latter has in turn been attacked by some mold belonging to the *Hyphomycetes*, and it is this second parasite that Dr. Mayr considers to be the teleutospores of the æcidium. But the whole structure is quite different from any teleutospore. The black, carbonaceous mycelium, very irregular in the shape and appearance of the cells, sometimes bears at the tips two-parted cells, but quite as frequently they are not two-parted, but more like what are called *Macrosporium* spores. It would be quite hopeless trying to name this young mycelium, for one finds very frequently just such forms resulting from the germination of *Pleospora* and other related genera. It is enough to say that the teleutospores of Dr. Mayr are merely the young stages of some parasitic *Pyrenomycete* which would be referred to the form genera *Cladosporium*, *Macrosporium*, etc., according to the division of the ultimate cells, which, in the present case, is not constant.

In conclusion we would express our indebtedness to Dr. Mayr for his courtesy in submitting, quite unsolicited, his original specimens to us for examination, and, although unable to agree with his determinations of the fungi, we gladly recognize his friendly treatment of a reviewer whose views differ from his own.

Notes of a Summer Journey in Europe.—V.

THE route from Zurich to Munich took me over Lake Constance to the quaint little harbor of Lindau, in Bavaria. Between Lindau and Munich there are large areas of planted Spruce-forests, and at this time they were looking in fine order and well kept. In many tracts, containing thousands of trees, the trunk of each tree was protected from invasions of ascending insect enemies by a band, presumably, of the same insect-lime which Professor Fernow has advocated so strongly in *GARDEN AND FOREST* (vol. iv., p. 142) and elsewhere. This precaution was particularly directed against the Nonne (*Liparis monacha*), a large moth, the larvæ of which are said to have done damage to the extent of hundreds of thousands of dollars to the coniferous forests of Bavaria and the adjacent countries in the summer of 1890. Close along the line of railway were myriads of young seedlings, and wherever there was an abandoned gravel-pit or a worn-out piece of soil it had been thickly planted with young Spruces, which would soon make profitable what would otherwise be waste land.

Of the trees planted in the streets of Munich, Lindens, Lombardy Poplars, the Red-flowering Horse-chestnuts, known as *Æsculus rubicunda*, and Planes (*Platanus*) seem to be the favorites. The Planes here were in poorer condition than in almost any other place visited where they were much planted, and the Lombardy Poplars were chiefly noticeable on some long streets leading out of the city. The healthiest trees noticed here were two double rows of the Red-flowering Horse-chestnut which partially surround the narrow park-like Promenade Platz. These trees (all grafted, of course) are planted about twenty-four feet apart each way, and give a dense cool shade without growing so high as to obstruct the light and air from buildings. The foliage maintained its characteristic dark green color, and although the trunks were unprotected, few of them showed any signs of mechanical injury. Within the Promenade Platz are well-arranged groups of shrubbery and a few unobtrusive beds of herbaceous plants.

Munich boasts a Royal Botanic Garden, situated well within the city, and of some interest in certain directions. Much pride is evidently felt in the large and high Palm-house, and also in the Alpine Garden, which is built of irregular sandstone-rocks containing innumerable pockets calculated to hold moisture. An attempt has been made to divide this Alpine Garden into sections according to the geographical distribution of the plants, but this arrangement does not seem to work well, or, at least, does not appear to be consistently carried out. Sections are marked out for European, Mediterranean, Taurian, Himalayan and other alpine floras, but the space devoted to each is necessarily absurdly small. Any such arrangement necessitates a good deal of duplication of species, and, of course, few botanic gardens can afford to do more than show a very few typical species of the different genera. The alpine here were in a very vigorous condition, and showed special care. Some of the plants grow so rampantly that they are with difficulty kept within bounds. Such plants as spread from underground shoots are not easily managed in an ordinary rockery because the roots and shoots get among the rocks, where it is difficult to cut them out.

Campanulas and *Potentillas* were the most conspicuous plants left in bloom. The tallest and most conspicuous of the Campanulas was *C. Americana*, three or four feet high, with its long spikes of blue flowers. Other more dwarf and more graceful species still blooming were *C. turbinata*, with wide-spreading white corollas; *C. thyrsoides*, with dense erect spikes of pretty white flowers, the corollas densely hairy within; *C. pusilla*, a very dwarf species, with light blue or white flowers, and a species of *Symphandra*, whose blossoms might easily be mistaken for those of a Campanula. A little *Aubrieta* made a good compact rockery plant for blooming at this season, while *Drypis spinosa* attracted attention by its innumerable small star-shaped, silvery white flowers.

As the temperature in winter here rarely goes lower than twenty or twenty-five degrees below zero of Reaumur, it is possible to grow some of the species of *Cistus* in the open air; and several plants of these shrubs were still bearing some of their pretty flowers, which, by their petals and stamens, seem to suggest an alliance between a wild Rose and a St. John's Wort. A handsome fruiting clump of our American Cranberry, growing in the rockery, was found to be planted in a hollow decaying log, which was sunk into the ground and filled with peaty soil.

The collection of herbaceous plants is arranged in good clumps and well separated; and, as would be expected, the composite plants were making the best show at this season (July 29th), although *Veronicas*, *Campanulas*, *Stachys*, etc.,

were also conspicuous. The collection of grasses and sedges was particularly in fine condition. As showing the care and trouble which is in some cases taken in the attempt to secure the best conditions for the rarer plants, it may be mentioned that specially constructed beds are allotted to the *Myricas*, *Andromedas*, *Vacciniums*, the moisture-loving *Kalmias*, etc. The foundations of these beds are made in the form of large flat tanks, with double sides, lined with cement. These tanks are filled with good-looking peaty soil, surrounded by and saturated with water. Yet, with all this care, the plants look miserable and do not seem to thrive, and, undoubtedly, most of them would do much better under ordinary garden cultivation in a good mixture of peaty soil and sand and with some slight shade from the direct rays of the sun. The plants here were suffering from want of drainage, for, although they like moisture, they do best when placed within reach of water by the roots, instead of being planted in it.

Several acres in the garden are set apart as an arboretum, or, at least, are specially devoted to trees and shrubs. There are no trees remarkable for size or rarity, and many of the shrubs suffer from the effect of being planted in grass instead of in beds under cultivation. A very good collection of wild *Roses* particularly suffered from this treatment. This custom of planting isolated specimens of shrubs in the turf prevails in a number of German gardens, but in none of those seen did it seem to be satisfactory, except with such kinds as were of vigorous, coarse growth. It may be argued that they grow among grass or herbage in a wild state, but those who use this argument lose sight of the fact that in nature these shrubs and other plants flourish well only where they have congenial soil, situation and neighbors. Moreover, they often grow in considerable masses or clumps together, thus affording mutual assistance and protection in shading the ground and keeping down weeds and other possible intruders. Except under very exceptional conditions and among the strongest-growing species, wild *Roses* and other plants of similar habit are certain to suffer from having grass growing closely about their roots and stems; certainly to see these plants, as isolated specimens dotting the turf, produces anything but a natural effect, while the bushes lose the great advantage which is gained by even a very slight cultivation. In rich soils and in turf composed of some of the more slender kinds of grasses they may do better than any I saw.

It seemed singular not to find any conifers among the trees, and to see our *Pines*, *Spruces*, *Firs*, etc., growing in pots or tubs, as though they were tender sub-tropical or tropical exotics. The smoke and soot of the city are said to cause the death of these evergreen species in a comparatively short time if left in the open air during the winters. Every autumn they are brought into cold houses or pits for protection. I do not know whether protecting the plants by canvas caps, or otherwise, and allowing them to remain out, has ever been tried, but it would seem to be worth while making some experiments in this direction, because the item of storage of the plants is considerable. The only evergreen conifer in the garden, permanently growing outside, was a poor, forlorn-looking specimen of the *Austrian Pine*, which was sixteen or eighteen feet in height.

In labeling the plants some small porcelain or enameled labels are used; but most of the permanent labels are made of galvanized iron, zinc or wood, cut into oval shape and fastened to wooden or flat bar-iron stakes. The surface of these labels is painted white, and the lettering gives both the Latin and a best-known German popular name.

Arnold Arboretum.

J. G. Jack.

Is Grafting a Devitalizing Process?—I.

PROFESSOR L. H. BAILEY, of Cornell University, read a paper on this subject before the Peninsula Horticultural Society at its meeting last week in Dover, Delaware. A portion of it is printed below, and the remainder will follow in a subsequent issue:

To the popular mind the process of grafting is akin to magic, and entirely opposed to the laws of nature. It is mysterious, and seems to represent the extreme power which man exercises over natural forces. And yet the operation is very simple, and the process of union is nothing more than the healing of a wound. It is in no way more mysterious than the rooting of cuttings, and it is not so unnatural if by this expression we refer to the relative frequency of the occurrences of the phenomena in nature. Natural grafts are by no means rare among forest-trees, and occasionally the union is so complete that the foster-stock entirely supports and nourishes the other. Cut-

tings, however, are very rare among wild plants; in fact, I know of but one instance in which cuttings are made entirely without the aid of man, and that is the case of certain brittle *Willows* whose branches are easily cast by wind and snow into streams and moist places, where they sometimes take root. But the mere unnaturalness of any operation has no importance among phenomena attaching to cultivated plants, for all cultivation is itself unnatural in this ordinary sense.

Nor is the union of cion and stock any more mysterious or unusual than the rooting of cuttings; in fact, it has always seemed to me to be the simpler and more normal process of the two. A wounded surface heals over as a matter of protection to the plant, and when two wounded surfaces of consanguineous plants are closely applied nothing is more natural than that the nascent cells should interlock and unite. In other words, I do not see why two cells from different allied stems should refuse to unite any more than two cells from the same stem. But why bits of stem should throw out roots from their lower portion and leaves from their upper portion, when both ends may be to every human sense exactly alike, is indeed a mystery. We regard healing as one of the necessary functions of stems, but rooting cannot be so regarded.

I have said this much by way of preface in order to free your minds of any feeling which you may possess that grafting is in principle and essence opposed to nature, and therefore fundamentally wrong. A large part of the discussion of the philosophy of grafting appears to have been random because of this assumption that it is necessarily opposed to natural processes.

It does not follow from these propositions, however, that grafting is a desirable method of multiplying plants, but that the subject must be approached by means of direct and positive evidence. During the last three years the opponents of the system of grafting have made the most sweeping statements of its perniciousness. This recent discussion started from an editorial in *The Field*, an English journal, which was copied in *The Garden* of January 26th, 1889, with an invitation for discussion of the subject. The article opens as follows: "We doubt if there is a greater nuisance in the whole practice of gardening than the art of grafting. It is very clever, it is very interesting, but it will be no great loss if it is abolished altogether. It is for the convenience of the nurseryman that it is done in nine cases out of ten, and in nearly all instances it is not only needless, but harmful. If we made the nurserymen give us things on their own roots, they would find some quick means of doing so." Profuse discussion followed for a period of two years, in which many excellent observers took part. Some of the denunciations of grafting are as follows: "Grafting is always a makeshift, and very often a fraud." "Grafting is in effect a kind of adulteration. . . . It is an analogue of the coffee and chicory business. . . . Grafted plants of all kinds are open to all sorts of accidents and disaster, and very often the soil or the climate or the cultivator is blamed by employers for evils which thus originated in the nursery. . . . If in certain cases grafting as a convenience has to be resorted to, then let it be root-grafting, a system that eventually affords the cion a chance of rooting on its own account in a natural way." "Toy games, such as grafting and budding, will have to be abandoned, and real work must be begun on some sound and sensible plan." "Any fruit-bearing or ornamental tree that will not succeed on its own roots had better go to the rubbish-fire at once. We want no coddled or grafted stuff when own-rooted things are in all ways infinitely better, healthier and longer-lived." These sweeping statements are made by F. W. Burbidge, of Dublin, a well-known author, whose opinions command attention. The editor of *The Garden* writes: "We should not plant any grafted tree or shrub so far as what are called ornamental trees and shrubs are concerned. There may be reason for the universal grafting of fruit-trees, though we doubt it."

I have not cited these quotations in any controversial spirit, but simply to show the positiveness with which the practice of grafting is assailed. And as the presumption is in favor of any practice which has become universal, these statements possess extraordinary interest.

The reasons advanced for these denunciations of grafting are three, so far as I can learn. These are, (1) the citation of numerous instances in which grafting (by which I mean both grafting and budding) has given pernicious results; (2) the affirmation that the process is unnatural; (3) the statement that own-rooted plants are better—that is, longer-lived, hardier, more virile—than graft-rooted plants.

1. Citations of the injurious effects of grafting are usually confined to ornamental plants, and the commonly cited fault of the operation is the tendency of the stocks to sucker and choke the graft. This fault is certainly common, but, on the other

hand, there are numerous instances in which it does not occur, as, for instance, in Peach, Apple, Pear and many other fruit-trees, and in many ornamental trees. In fact, it is no more common, in the plants which have fallen under my observation, than is the pernicious suckering of plants grown from cuttings, as in the Lilacs, cutting-grown or sucker-grown Plums and many other plants, in which suckers must be assiduously kept down or they will choke the main stem which we are endeavoring to rear. These remarks apply with equal force to every citation which I have ever seen of the ill effects of grafting. The cases simply show that the operation has been a failure or is open to objections in the particular instances cited, and afford no proof that there may not be other plants upon which grafting is an entire success. For myself, I am convinced that grafting has been too indiscriminately employed, and it is apparent to every one that there have been many failures in the practice. But this does not prove grafting wrong any more than malpractice of physicians proves that the science of medicine is pernicious. If there are plants upon which grafting is entirely successful, then all must agree that the operation itself is not wrong, per se, however many cases there may be to which it is not adapted.

2. The proposition that grafting is unnatural, and therefore pernicious, is a fallacy. In the first place, there is nothing to show that it is any more unnatural than the making of cuttings, and if naturalness is proved by frequency of occurrence in nature, then graftage must be considered the more natural process of the two, as I have already shown. One of the most determined writers upon this subject has said that "it is quite fair to say that raising a tree from seed, or a shrub by pulling it in pieces (cuttings), is a more natural mode of increase than by grafting." I cannot understand by what token the author is to prove that pulling a plant in pieces is more natural than grafting; and there has been no attempt, so far as I know, to show that it is so.

But the whole discussion of the mere naturalness of any operation is really aside from the question, for every operation in the garden is in some sense unnatural, whether it be transplantation, pruning or tillage; and it is well known that these very unnatural processes may sometimes increase the longevity and virility of the plant. Plants which receive an abundance of food and are protected from insects and fungi and the struggle with other plants are better equipped than those left entirely to nature. It is the commonest notion that cultivation is essentially an artificial stimulus; that it excites the plant to performances really beyond its own power, and therefore devitalizes it. But this is a fallacy. All plants and animals in a state of nature possess more power than they are able to express, and they are held in a state of equilibrium, as Mr. Spencer puts it, by the adaptations of environment. Once the pressure of existing environments is removed, the plant springs into the breach and takes on some new feature of size, robustness or prolificacy, or distributes itself in new directions. The whole series of benefits which arise from a change of seed is a familiar proof of this fact, so that if cultivation, domestication, or, in other words, unnaturalness, may be sometimes a stimulus, it is not necessarily so. Cultivation differs from natural conditions more in degree than in kind. Or, as Darwin writes, "Man may be said to have been trying an experiment on a gigantic scale; and it is an experiment which nature during the long lapse of time has incessantly tried."

Plant Notes.

Some Recent Portraits.

THE new volume of the *Botanical Magazine*, the one hundred and fifth of the entire series, opens with a figure (t. 7212) of the great Iris of Lord Howe's Island, *Moræa Robinsoniana*, whose portrait has already appeared in these columns, and whose flowering last summer at Kew, for the first time in Europe, was one of the floral events of the English capital. The other figures are devoted to *Chirita depressa* (t. 7213), a native of China, an herbaceous plant with small bright purple flowers. This is a member of the family of Gesneraceæ, in which are many plants which have been wonderfully improved by cultivation, and it is not improbable that the present species may, with careful attention and selection, develop into a good garden-plant. *Cirrhopetalum Thourasii* (t. 7214), an interesting, although not very showy-flowered Orchid, upon which Lindley long ago founded the genus, and a native

of Mauritius and the islands of the south Pacific Ocean. *Iris Fosteriana* (t. 7215), a bulbous species, discovered in 1884 by Dr. Aitchison in Afghanistan, where he found it growing plentifully at Badghis "in dry soil on the low hills at an elevation of three thousand feet above the sea-level." From a horticultural point of view this plant differs from all its allies in the variety of the colors of the different parts of the flower, the outer segments being bright yellow, with a spreading blade streaked with black, while the inner segments are bright lilac. The figure is from a plant which flowered in Professor Foster's garden at Cambridge, for whom Mr. Baker has named the species. *Primula Poissoni* (t. 7216); this is one of the new Chinese plants discovered by the Abbé Delevay, and raised in the Paris garden from seeds sent home by him. Like *Primula Japonica* and *Primula imperialis*, it produces superposed whorls of flowers; these are bright rosy lilac, and are produced in great profusion, the Kew plant from which the figure is made having produced eight scapes of flowers and flowered itself to death. The facility with which Primroses can be improved by cultivation is shown by the fact that the native specimens of this species are very small, with leaves only two or three inches long and a solitary slender scape with only a few flowers in a whorl, whereas on the cultivated plant the flower-stock was fully two feet high and as thick as a goose-quill.

Foreign Correspondence.

New Garden Plants of 1891.—II.

STOVE AND GREENHOUSE PLANTS.—Exclusive of Orchids, the best new stove and greenhouse plants introduced into cultivation last year must be credited to Kew. Few trade collectors think it worth while to pay any attention to foliage or flowering plants other than Orchids, for the reason that, as a rule, there is not much money in them. The botanical gardens in the colonies and numerous correspondents in various parts of the world, however, send to Kew various interesting and good decorative plants, and these are eventually distributed among nurserymen and others who desire to try them. Of the fifty or so new stove and greenhouse plants recorded the following are of most promise horticulturally:

ALBERTA MAGNA.—Mr. W. Bull offered this plant in his catalogue of new plants for last year. It has been in cultivation several years at Kew, but, so far as I know, it has never yet flowered in England. It is rubiaceous, closely allied to *Cinchona*, which it resembles in habit and foliage; the flowers, which are small, are in dense panicles, and colored bright red. It will most likely prove a good greenhouse-plant, as it comes from a high altitude in Natal. The treatment which suits *Luculia* ought to answer for the Alberta.

ALLAMANDA WILLIAMSONII, Hort.—Probably only one of the many forms of the variable *A. cathartica*, but differing from those previously known in gardens by its shrubby habit and floriferousness. It has been brought into notice by B. S. Williams & Son.

ARISTOLOCHIA GIGAS, var. STURTEVANTII, Watson.—This came to Kew from Mr. Sturtevant. It flowered freely in one of the tropical houses, and, so far at any rate as Europe is concerned, it was the most remarkable new plant of the year. It is named in compliment to Mr. E. D. Sturtevant, for reasons stated in GARDEN AND FOREST, vol. iv., p. 546.

BROWNEA CRAWFORDII, Watson.—This is a hybrid between *B. grandiceps* and *B. macrophylla*, which flowered at Kew last year, and was named in compliment to the late W. H. Crawford, of Cork, who raised it. In the size of the inflorescence and color of the flowers it is even superior to *B. grandiceps*.

BAUHINIA GALPINI, N. E. Br.—This is a most promising flowering-shrub for the warm greenhouse, which has been introduced to Kew from the Transvaal. It has two-lobed

Fig. 9.—A New England Winter Scene.—See page 37.

leaves and crowded racemes of large handsome crimson flowers, borne on numerous twiggy branches. It grows to a height of about six feet. A figure of it was published in *Hooker's Icones* last year (pl. 1994).

CRINUM ROOZENIANUM, O'Brien.—This is said to be near *C. Americanum*, although the growth resembles *C. erubescens*. The flowers are four to twelve in an umbel, six

to eight inches long, with recurved segments three to four inches long and three-fourths of an inch wide, white. It has been introduced from Jamaica by A. Roozen & Co., Haarlem.

COCOS PYNARTII, Hort., is a seedling form of *C. Weddelliana* with very narrow leaf-segments. It was raised by Monsieur Pynaert, of Ghent, and figured in the *Revue de*

Horticulture Belge last year (p. 91, fig. 15) under the name of *C. minima glauca*.

CLIVENCHARIS PULCHRA, Hort.—It was stated last year that L. Van Houtte, of Ghent, had succeeded in raising a bigeneric hybrid from *Clivea* and *Eucharis Amazonica*, of which further detail would presently be published. Such a cross, if successful, cannot fail to be of exceptional interest.

DIPLODENIA ILLUSTRIS, var. *GLABRA*, is a handsome stove-climber with a woody root-stock, annual climbing stems, thick ovate leaves, and large rosy red flowers. It has been introduced from Brazil, and flowered at Kew last year.

EPIPHYLLUM GAERTNERI was introduced several years ago under the names *E. Makoyanum* and *E. Russellianum*, var. *Gaertneri*. It was at first supposed to be a hybrid between *Cereus* and *Epiphyllum*, but it now proves to be an introduction from Brazil and a third good species of *Epiphyllum*. It is a beautiful stove-plant, at least equal to the best of the many varieties of this genus grown, and at the same time abundantly distinct from them all. A figure of it was published in the *Botanical Magazine* (t. 7201).

IMPATIENS MIRABILIS.—This extraordinary species has lately been noticed in GARDEN AND FOREST. It is a native of Malaya, where it forms an erect, naked, succulent trunk four feet high, and as thick as a man's leg; leaves nearly a foot long, and large inflated, fleshy, golden yellow flowers. It flowered at Kew, and was figured in the *Botanical Magazine* (t. 7195).

LILIUM LOWII, Baker.—This is a new species similar to *L. nepalense*, with white flowers. It has been introduced from northern India by Messrs. H. Low & Co. (See GARDEN AND FOREST, vol. iv., p. 352.)

MOREA ROBINSONIANA is not a new plant, but its flowering at Kew last year for the first time revealed its true character, which is that of a handsome floriferous *Iris* of exceptional dimensions. It is figured in GARDEN AND FOREST (vol. iv., p. 552.)

NERINE PANCRATIOIDES, Baker, is a new edition to the genus which Mr. O'Brien has introduced from Natal. It has long narrow leaves, a scape two feet high bearing an umbel of from twelve to twenty flowers one inch long, with small square bifid scales between the filaments.

PRIMULA IMPERIALIS, Jungh.—This is the gigantic Primrose from the mountains of Java, which was raised at Kew from imported seeds and flowered for the first time last year. It has a broad rosette of leaves each fifteen inches long by five inches wide, an erect scape three to four feet high, bearing whorls of deep yellow flowers.

PRIMULA POISSONII, Franchet, is a new and beautiful species from Yun-nan which flowered at Kew in June last. It resembles *P. Japonica* in habit, but differs in the leaves and in the color of the flowers, which is rich rosy mauve with a yellow eye. A single plant of this species has produced no less than twelve scapes in one season.

STREPTOCARPUS GALPINI, Hook. f.—I described this in GARDEN AND FOREST, vol. iv., p. 534, from plants which have been introduced at Kew from the Transvaal. It is the prettiest of all the species of this genus.

THRINAX MORRISII, Wendl.—This was discovered by Mr. D. Morris, the Assistant Director at Kew, in the island of Anguilla, in the West Indies. It differs from all known species of *Thrinax* in the dwarfness of its stature, none of the many mature plants seen by Mr. Morris exceeding three feet in height. It has elegant foliage, and promises to be a useful garden Palm.

TULBAGHIA NATALENSIS, Baker, is a Cape bulb with no more beauty than *Mignonette*, but, like the latter, it has the charm of delightful fragrance. It has been introduced to Kew from Natal. *T. alliacea* is cultivated for the sake of its purple flowers. Its linear leaves have a strong onion-like odor.

WAHLENBERGIA UNULATA, Cham.—A straggling herbaceous plant which may be grown in suspended baskets, so that its thin leafy stems may hang and display its campanulate

deep blue flowers. It has been introduced from the Cape to Kew.

Among popular greenhouse-plants perhaps the most noteworthy additions last year were the beautiful dwarf *Cannas*, whose large richly colored flowers and good nature under ordinary cultivation have made them prime favorites in England. Two pretty Japanese varieties of *Azalea amœna*, hardy in England, were sent out by J. Veitch & Sons. This firm have also added many new varieties of greenhouse *Rhododendrons* and *Hippeastrums*.

HERBACEOUS PLANTS.—There was an extraordinary number of varieties of popular herbaceous plants introduced last year, such things as *Dahlias*, *Gladioli*, *Pæonias*, *Carnations*, *Rudbeckias*, *Delphiniums* and *Iris*es being considerably reinforced by additional sorts of first-rate character. Of new species there were very few, the best of them being as follows: *Chionodoxa grandiflora*, a variety of *C. Luciliæ* with erect racemes and larger flowers than the type. It was previously known as *C. gigantea* (T. S. Ware & Co.) *Galanthus Alleni*, Baker. A pretty addition to cultivated *Snowdrops*, characterized by short broad leaves and pure white flowers (Caucasus). *G. nivalis*, var. *Elsæ*, Burbidge, a variety with larger flowers and broader leaves than *G. Corcyrensis*, from Macedonia. Another variety, named *Racheliæ* by Mr. Burbidge, has larger flowers than the last-named, and blossoms in October and November. *Iris Fosteri*, Baker, is a handsome species of the *Caucasica* group. It has yellow flowers blotched with deep violet. *Lilium Brownii*, var. *chloraster*, Baker, is a new introduction to Kew from western China, and differs from the type in having broader leaves, larger flowers, with a broad green midrib to each segment, and deep red pollen. *L. Martagon* × *Hansonii*, Baker, is a hybrid raised by C. G. Van Tubergen, Haarlem, from the two species indicated in the name. *Watsonia densiflora alba* is a very pretty Cape bulb which has so far stood out-of-doors at Kew, where it flowered for the first time last year. It has erect spikes eighteen inches high, with the flowers in a dense head like a ripe wheat-ear; pure white.

A CORRECTION.—*Miltonia vexillaria*, var. *Sanderiana*. The plant to which I referred under this name in GARDEN AND FOREST (vol. iv., p. 545), and again in the list of new plants of 1891 (vol. v., p. 31), had, I find, been previously figured and described in *Revue de l'Horticulture Belge*, 1891 (p. 73), under the name of *M. vexillaria*, var. *Leopoldiana*, Reichb. f. "One of the prettiest and rarest of the varieties of this *Miltonia* is this which was dedicated by Reichenbach to Leopold II. It had been received by Monsieur Paynaert direct from Monsieur Paten, of Antioquia, in Colombia. It has been exhibited before the Horticultural Society of Belgium and the Royal Society of Agriculture and Botany at Ghent, and was unanimously awarded a certificate of merit."

Christmas Roses.

IT is only within the last few years that these charming hardy midwinter flowers have become so popular in English gardens, and curiously enough the desire on the part of a few specialists to arrive at something like finality in the nomenclature of *Helleborus niger* and its varieties, has been the means of bringing to light varieties unheard of previously. While the controversy was in progress distinct varieties were cropping up all over the country, each with its special markings, different time of flowering, etc. The varieties *altifolius*, *major* and *angustifolius* may perhaps be taken as the standard ones. They were pretty well known to the older botanists, and were the varieties usually found in general collections. To these have been added, within recent years, *vernalis*, *Riverston*, hybrid *Caucasicus* of gardens, the *Bath* variety, the *Brockhurst* variety, *Madame Fourcade*, *St. Brigid*, *W. Brockbank*, etc., some of them having probably been in gardens for many years, and grown simply as the Christmas Rose. The gathering of a collection together was the inevitable result of so much correspondence, the comparing and describing of which

has been very gradual. In addition to these, however, a host of new forms have cropped out as a result of selection from seedlings raised in this country, and also from the numerous importations that are now of annual occurrence. North Germany, the Austrian Tyrol and other well-known localities supply our markets, but so many equally good, if not better, forms are being raised from seed that we will soon be able to dispense with collected roots altogether. A collection of plants from the Austrian Tyrol, which we had the pleasure of going over in flower, were plentiful in forms resembling Madame Fourcade, Riverston hybrid and others, which led to the conclusion that all or most of these varieties were at one time or other imported.

Our chief difficulty with Christmas Roses in the open air in England, and which we suppose will be greatly aggravated in America, is the uncertainty of our season, especially mid-winter, when the flowers are most in request. A simple covering of glass is of no use whatever, and if the flowers are wanted for cutting, and wanted clean, they must be grown indoors, and out of the reach of frost. We believe that when the plants are gently forced the flowers are larger and cleaner, and last considerably longer in water. A large group of Italian forms have shown beautiful flowers for many weeks now in the wild garden at Kew, and although invisible during frosty weather they are up as fresh and bright as ever when a change takes place. They have been here without any special cultivation for several years, and every winter brings a greater abundance of flowers, which are much admired by visitors. This mode of dealing with surplus stock will be found a very advantageous one even in private gardens, and large quantities of flowers for cutting could in this way be secured. Hellobores, at any rate the niger section, are gross feeders, and the question of manure, or no manure, in their cultivation, will depend largely on the nature of the soil in each particular locality. Where the soil is heavy and rich little or no artificial feeding will be required, but where it is light or sandy a sprinkling of heavy loam should be given in addition to the manure. In the latter soil, and in dry seasons especially, a mulching of leaves or other material during summer will be necessary. Where Christmas Roses are annually lifted and potted for greenhouse decoration it is essential to keep a double set, lifting them alternately, and never planting back those used for the house, until all danger from frosts is past, otherwise the young tender leaves are destroyed, and the plants greatly weakened.

Of the varieties of *H. niger*, *altifolius*, also called *maximus*, is one of the commonest in English gardens, and perhaps the finest of the whole niger group. When grown in shady sheltered situations the flowers come pure white, but where exposed they are shaded with rose on the outside, which, in our opinion, enhances rather than detracts from their beauty. The leaves are large, leathery, and the stalks as well as the flower-stems are deep purple.

Angustifolius is apparently an old garden-plant, the name being well known in Sweet's time. It was not, however, until 1876 that Miss Hope's variety was recognized as the true *H. niger angustifolius*. The flowers are quite three inches in diameter, white, and often tinged with rose on the outside; the leaf-divisions narrow, and the stalks and flower-stems green, sparingly spotted red. There are two other well-marked forms of *angustifolius* to be found in gardens. The Brockenhurst form, in which the leaf-stalks and flower-stems have scarcely a trace of purple markings, usually bears two flowers; the other, St. Brigid's Christmas Rose, has pure snow-white flowers somewhat cup-shaped, with flower and leaf-stalks of a rich apple-green.

The Bath variety is almost intermediate between *H. niger* and *H. niger angustifolius*. The flowers are large, flat, pure white; the flower and leaf-stalks spotted red, the latter slightly furrowed.

Caucasicus is a very misleading name, there being a species, *H. caucasicus*, belonging to the *Orientalis* section. It has been widely distributed in England under the above name, and it is one of the most profuse-flowering varieties we possess. The leaflets are coarsely and sharply toothed, and much resemble the Italian forms; flowers pure white, tinged rose on the outside; the flower-stalk densely spotted red, and the petiole stout and deeply furrowed.

Madame Fourcade is a charming variety belonging to the *altifolius* set. The flowers are nearly three inches in diameter, pure white; the flower-stalk and petiole red-spotted, the latter slightly furrowed.

Of the variety major there appear to be a large number of forms in cultivation, although varying but slightly from the old type. The leaves are very massive, the flowers large, white, with a pale pink tinge.

Riverston hybrid might almost be classed as a form of *angustifolius*. It is said to be a hybrid, but we fail to find any justification for this statement. It is a robust plant, with flowers nearly four inches in diameter, white, tinged rose. The petioles are green, and the flower-stalks red-spotted.

Vernalis seems allied to the variety *Caucasicus*. The flowers are large, white, tinged rose; petioles green, deeply furrowed; the flower-stalk red-spotted. A useful form, and a free flowerer.

W. Brockbank, named as a fitting compliment to Mr. Brockbank, who has done much to make this family popular in England, is very distinct, remarkable in the flowers being so deeply cupped; flowers about three inches in diameter, pure white; petiole and leaf-stalk sparingly spotted.

There are numerous other forms equally desirable, but the above will suffice to show the wealth of hardy midwinter flowers within the reach of all.

Kew.

D. Dewar.

Seasonable Hints.

THE propagation of stock for the coming season is an operation that should be now looked after, the midwinter and early spring months being specially favorable for rooting many cuttings. Fine Cocoa-fibre is a very useful material in the propagating-frame, both for holding plunged cutting-pots and for use in such pots in place of soil or sand, since it retains moisture for a long time and is a good conductor of heat.

I have used this fibre successfully for a variety of cuttings, such as those of *Pandanus Veitchii*, *Ananas*, *Ficus*, *Crotons*, *Calatheas*, etc. It is also an excellent material in which to plunge freshly potted plants of delicate kinds, and is a cleanly and durable substance for such use.

Bouvardias now claim attention, whether the root-cuttings or tops are used. In the latter case the tips of the shoots alone are valuable, and these should be quite soft and succulent. It is a waste of time to put in hard cuttings of Bouvardias, and for most of the single varieties, with the exception of *Bouvardia jasminiflora*, the system of root-cuttings is the least troublesome.

Two excellent plants that should be included in all collections are *Asparagus plumosus* and *A. tenuissimus*. Their foliage is of special value for cutting, as it will keep in water for weeks. Unfortunately, *A. plumosus* is somewhat difficult to increase, as the cuttings seldom root satisfactorily, and division of the roots is a rather slow process, but if planted out in a greenhouse like *Smilax* it will sometimes seed, and then with reasonable care a stock may soon be secured. *A. tenuissimus* is readily propagated by cuttings, which may be made from almost any firm side-shoots, and will usually root in a few weeks.

Canna-seeds may be sown now, since there is an advantage in sowing them early, for sometimes they are rather obdurate about germinating. Many growers soak or scald these seeds, and some go to the extent of filing a hole in the shell in order to assist germination, but I have not found these processes necessary. When the seed-pans are placed in a warm house and plenty of moisture is given them I have lost but a small percentage of seeds. I have also tried soaking the seeds of various Palms for twenty-four to forty-eight hours before sowing, but have been unable to prove that much time can thus be saved in the period of germination.

The chief essential in the raising of Palms from seed is a moderately high temperature and fresh seeds, and little difficulty will then be found in inducing most species to germinate, though the time necessary for this varies greatly with different species. For instance, I have had seeds of *Livistona chinensis* germinate in ten days, and I also have now some seeds of *Attalea Cohune*, the *Cohune Palm*, that have been planted for two and a half years, and, though perfectly sound, they show no sign of germination. These are, however, among the extreme cases, though some of the *Kentias* are also slow, the irregularity of their transmission from their native land probably having something to do with the variations in the time of growing, and it is very likely also that some of the seeds are not perfectly matured when gathered. Of course, the operation of raising Palms from seeds is an interesting one, either for the amateur cultivator or for the professional, but it is well to remember that the retail buyer of Palm-seeds may not be able to secure as fresh stock as the large commercial grower, and consequently he may not secure so good a result.

The cleaning of any insect-infested plants should receive attention before the spring potting is done, so that the plants will be in condition to go forward; this precaution is especially

applicable to Palms. Fumigation with tobacco-stems is the best preventive for green-fly and thrips, and should be applied at regular intervals.

Holmesburg, Pa.

W. H. Taplin.

Begonias.

AMONG the numerous new Begonias of the shrubby section introduced recently, the crosses between *B. Olbia* and *B. rubra* seem especially striking, handsome and useful. *Souvenir de F. Gaulain*, *President Carnot* and *Bismarcki* are somewhat similar in general effect, the former having the darkest flowers and the latter the lightest. The leaves are long, finely notched and satiny, emerald-green above and reddish beneath. While similar in general effect, they have marked distinctive qualities. *President Carnot* is especially attractive, the upper part of the leaves being suffused with a reddish bloom, which has a very handsome effect. The flowers of all the varieties are large and borne in profusion. They are rather tall-growing subjects, but the limited space at my disposal will not allow me to let them grow to ascertain whether they possess the vigor of *B. rubra*. Apparently, they would be intermediate in size between the parents if well grown.

Hybrids and seedlings of *B. metallica* do not seem any great improvement on the parent as far as tried. *B. metallica* is one of the best of foliage-plants, free-growing, with a distinct character in its well-marked veins. The hybrids all have a weakly pallid look from absence of the strong veinings, and do not seem to have gained in freedom of flowering. These remarks especially apply to *B. cuprea* and *B. velutina*, which are seedlings. *B. pictavensis*, one of the new hybrids (with *B. Scharfiana*), is rather better, but does not, to me, seem as attractive as the latter parent.

In the tuberous section the most important offering this year is a new fragrant species, *B. fulgens*, by the Messrs. Lemoine. As tuberous Begonias are invaluable for greenhouse decoration in summer, the infusion of a distinct fragrance to the present hybrids will be a great gain. There seems a premonition of a great boom in hybrid tuberous Begonias this year for bedding purposes. Certainly they have their uses for that purpose, and well-selected kinds, started in a cool place and brought on slowly, average very well as out-of-door flowers if carefully staked and given proper attention. I think, however, that no one who has grown them largely will consider them a satisfactory bedding plant in the same sense that the Geraniums are satisfactory—that is, as always reliable growers, producing a maximum of effect with a minimum of care. Even the sturdiest of them require staking, as the hold of the shoots on the bulbs is of the slightest, so that a wind will twist them off, and the black rust, or some fungus, is very partial to the shoots in certain conditions of the soil. If bedding effects are attempted, reserve plants should be grown to replace losses. As wet-weather flowers they are certainly superb, remaining in perfect condition after rains which entirely wash out ordinary flowers. To those not addicted to the bedding-habit, and who are not quite satisfied with mere big flowers, may be commended the tuberous species, which, without exception, are all charming, each with character peculiar to itself. It is singular that, as a race, tuberous Begonias are free from objectionable colors. Only when crossed with *B. Socotrana* have I noticed any magentas; but this color is, I think, never found among the summer-flowering kinds.

Elizabeth, N. J.

J. N. Gerard.

Winter-flowering Aquatics.

WATER-LILIES are naturally summer-flowering plants, but it is no longer a matter of question that their loveliness may be enjoyed in the depth of winter. I have never been without flowers of Water-lilies of some varieties since the closing of the season for them out-of-doors; and in the greenhouses at Prospect Park, Brooklyn, many beautiful flowers were to be seen at Christmas-time and into the new year. As it is the aim of the managers, however, to have flowers for the summer decoration of the park lakes, the temperature of the houses where the Water-lilies are now placed has been lowered to induce rest, otherwise they would have kept on blooming, and as it is, there are yet flowers, though fewer in number and smaller in size. An amateur in the vicinity of the park has a unique water-garden where tropical *Nymphæas* are always in bloom, and other aquatics are seen in summer luxuriance. These tropical varieties of *Nymphæa* are the ones suitable for winter-flowering, and plants which have been grown in tubs or tanks out-of-doors will continue to bloom through the winter months if placed in water where the temperature does not fall below sixty-five degrees. In the stove-

house but little pipe is needed in a tank to keep it at a temperature of seventy degrees. The difficulty I have experienced with heated tanks is that they become too warm. Plants of the Zanzibar Water-lily, of the blue Lotus of the Nile (*Nymphæa cœrulea*) and of *N. scutifolia* will do well in tubs where tanks cannot be provided, but, of course, the latter are preferable where space can be secured.

An essential point in the cultivation of Water-lilies in winter is to get all possible light and sunshine. A tank from twelve to fifteen inches deep will suffice for planting out winter-blooming Lilies. These should be specially selected—that is, they should be either seedlings of the type of *Nymphæa Zanzibarensis* or of plants somewhat retarded during the early part of the season. The night-blooming varieties will flower well and remain open a great part of the day. A tank eight feet wide and eighteen inches deep would require, perhaps, a two-inch pipe, although I find a one-inch pipe too large in a tank sixteen feet long, four feet wide and eight inches deep. Eighteen inches would be deep enough for immersing tubs. The soil used should be thoroughly rotted manure and rich loam, as has been recommended for outdoor planting. So far as I have observed, Water-lilies are quite as fragrant in winter as in summer, although in winter the blooms may be smaller where they do not enjoy the most favorable conditions.

Aponogeton distachyon is another useful winter-flowering water-plant which will bloom freely in an ordinary greenhouse. Another is *Pistea stratiotes*, a pretty floating plant, with light green woolly foliage, which is always attractive. *Richardias*, or, as they are commonly called, *Callas*, can be associated with other aquatics, and their flowers give a charming effect to the water-garden in winter. *Azolla Caroliniana* (Floating Moss) is an interesting plant, and so is the Water Hyacinth and the Parrot's Feather (*Myriophyllum*), but they are better in greenhouse temperature, to check too rank a growth. *Cyperus alternifolius* is useful in connection with flowering aquatic plants, very ornamental anywhere, and good for cutting purposes. The Egyptian Papyrus, too, is a most graceful plant for greenhouse decoration, and should never be omitted from the winter water-garden.

Where there is space for groups of ornamental foliage-plants like Palms, Cordylines, Crotons, *Dracænas*, *Marantas*, etc., a delightful background can be made in winter, especially for a tank of irregular outline on the ground level or slightly raised above it. This, however, needs a large house, so as to afford ample light, say, sixty by twenty-five feet, and larger. Of course, there is no end to arrangements which can be made with these and other plants with decorative foliage, while Ferns and other low-growing things can be used on the water's margin or to carpet the naked ground.

Dongan Hills, N. Y.

Wm. Tricker.

Citrus trifoliata as a Hedge-plant.

THE proved hardiness of this plant, even in the north-west, makes it certain that for the purposes of a defensive hedge it is more completely adapted than any plant yet introduced. Its dense and compact habit of growth and armament of long spike-like spines, pointing in every direction on the rigid branches, soon make it impenetrable even by the tough-skinned razor-back hog of the south, to which a barbed wire fence affords a pleasant irritation. In reply to a letter concerning this plant, Mr. P. J. Berckmans, of Augusta, says: "I have fruited *Limonium trifoliatum* (?) nearly ten years, having introduced the first plant from Japan in 1873, and have grown yearly since a large stock of it. I have also a hedge of it nearly half a mile long. We have advertised it as a hedge-plant for several years past, but have been unable to raise enough to fill the demand so far, owing to the scarcity of seed." Mentioning this to a friend to-day, he remarked that Florida ought now to be able to furnish all the seed needed, and he added that twelve to fifteen bushels of these little oranges went to waste on his place at Lake City last autumn, and if the proper effort was made any quantity of the seed could be had in Florida.

The fact that this plant is a member of the *Citrus* family has deterred many people at the north from making experiments with it, but wherever planted I have so far heard of no injury to it from cold, and if the experiment stations in all the northern states would test it thoroughly the degree of cold it can endure may soon be determined. In my own experience ten years ago a temperature of eighteen degrees below zero at night, and four degrees below at noon, with bright sunshine, did not injure young plants in the slightest degree. The compact and dwarfish habit of the plant will make a hedge of it much more easy to keep in shape than the rank and unruly *Maclura*, and the ornamental character of its sweet flowers,

and the profusion of its golden fruit in October, will render a hedge of it very attractive. As a single specimen on a lawn it is an object of rare beauty.

Raleigh, N. C.

W. F. Massey.

[*Citrus trifoliata* produces flowers and fruit in sheltered positions in the neighborhood of this city; but it is not sufficiently hardy in the northern Atlantic states to be used successfully as a hedge-plant. In New England it is generally cut to the ground every winter, and does not flower. It would be interesting to know in what part of the north-west its hardiness has been proved.—Ed.]

The Pin Oak (*Quercus palustris*) abounds here in its wild state, and, whether wild or planted, it commands universal admiration. The downward tendency of the lower tiers of branches and the finely divided, shining green leaves give it a distinct appearance among other Oaks, and its rapid growth should commend it to all planters. One reason why the various Maples are so largely used is that they can be transplanted easily and successfully. It ought to be more generally known that the Pin Oak may be transplanted with just as much safety as the Maple. I have seen long avenues planted with good-sized Pin Oaks without the loss of a single tree. Those familiar with the roots of various Oaks know how this species differs from most other Oaks in this particular. The Pin Oaks have a mass of fibrous roots instead of the few prong-like roots of most other kinds. Practical planters make all Oaks live by pruning them judiciously. The Pin Oak has the advantage of needing but very little pruning, because its numerous roots will carry it through even if the branches are not shortened in.

Germantown, Pa.

Joseph Meehan.

Correspondence.

The Senecios of the Canary Isles.

To the Editor of GARDEN AND FOREST:

Sir,—I notice with pleasure in Number 192 of your journal that Mr. Watson invites attention to the long-neglected Senecios of the Canary Islands. In the spring of 1884 I had the opportunity of admiring these charming flowers growing at the feet of ancient Laurels in the gorges of the Canaries. This archipelago is the true home of that class of Cinerarias or Senecios, for which Webb proposed the new generic name, *Pericallis*.

In my *Specilegium Canariense* (see *Engle's Botanisches Jahrbücher*, 1887) I have enumerated half a score of different forms, but the principal types of interest to us now are the following:

1. *Senecio appendicularis* (syn. *S. populifolius*) is distinguished by its leaves, which are deep green above and of a cottony white color beneath, and resemble altogether the leaves of the White Poplar. The corymbs are very dense, and the flowers almost always white.

2. *S. Heratieri* is a slender plant, almost rampant, with few-flowered, often one-flowered corymbs, but with large, bright rose-colored flowers. This is a plant of the mountain of Teneriffe, growing at an elevation of about 6,000 feet, and never attaining the slender, many-flowered habit shown in the figure on page 509 in the above-mentioned number. It is a plant long cultivated, but its native land is not, as Mr. Watson states, the island of Madeira. It is peculiar to Teneriffe. The only plant of this group found on Madeira (see the excellent catalogue of the plants of Madeira by Monsieur E. Casson in the *Bull. Soc. France*, 1868) is the *S. Maderansis*, which is akin to *S. appendicularis*, but still differs considerably from that species.

3. *S. Tussilaginus* is very common in shady places on the Canary Islands; it is slender, with firm branches and very large leaves, and spreading corymbs composed of bright rose-colored flowers. This plant is probably the parent of our cultivated Cinerarias and of numerous varieties. The wild type is very inconspicuous as compared with our greenhouse Cinerarias.

4. *S. papyraceus* is confined to the bay-woods of the Ile de Palma, and is a very remarkable species, two feet to two feet and a half high, with superb, dark, shining foliage, and irregular corymbs composed of about a hundred flower-heads of a brilliant rose-carmine color. One must see this truly admirable plant in order to realize how the resplendent flowers glow like fire in the deep, sombre shadows of Canarian trees like the *Phœbe Barbrisana* and *Oreodaphne fœtans*. The plant, through its great beauty, has become the favorite flower

of the inhabitants. Every child of Palma knows it by the name *Cima*, and in Spain one often hears this refrain:

Todas las flores se crian en Mayo
Menos la *Cima* que no se hallo.

This effective plant would be an acquisition, and it would ripen its seeds readily in our cool greenhouses.

5. *S. cruentus* is the loveliest of all the gems of this beautiful genus. I could hardly express my pleasure and surprise when I first noticed at a distance this superb plant at the foot of old Perseas, above La Florida, at an altitude of more than 5,000 feet. It is quite slender, fifteen to eighteen inches high, with large radical, reniform leaves of a clear purple tint. Branches, leaves and all, even the hairy down of the leaves, were of this color. It is altogether unique in its way, glittering like a flame, and visible at a considerable distance. The flowers have the same color, disposed in irregular corymbs, which are small for the genus. This is a plant whose vegetative parts have assumed a pure luminous color which properly belongs to the corolla only. What a welcome would it receive in our gardens if it would always retain this color when raised from seeds. But the seeds which germinated with me at Bâle produced both green and red plants, quite different from their mother-plants. For all that, I do not doubt that by a careful selection it is possible to obtain and maintain the beautiful race that exists on Teneriffe; it is a plant by the side of which *Lobelia cardinalis* seems really dull and insignificant.

I am sure that nothing could be more interesting and meritorious than the propagation by means of seeds of these admirable Senecios in your gardens. In the southern states, in Carolina, in Georgia, I am sure that they could live in the open air, for on Teneriffe they are found at an altitude where it is quite cold during the winter. There is nothing easier than to obtain the seeds through the numerous inhabitants that take interest in the flowers of their charming country.

I mention only Mr. Wildpret, the gardener of a beautiful garden of acclimatization in Orataba, W. Teneriffe, and Dr. Perez, of the same place. I may add that just as Madeira has only one species of these plants, the Azores also possess one species in the very pretty *S. malvæfolius*, a rather large plant with rich corymbs of bright crimson-colored flowers, which I received through the kindness of Dr. Bruno Carreira, of Ponta Delgada, on the isle of St. Michel.

The botanists who read this little article, the object of which is to draw the attention to a series of plants, charming, but much neglected, will find a complete enumeration of all the forms and species in my *Specilegium Canariense*, pages 147 to 149.

We may venture to hope that, through the introduction of natural forms of Senecio, we shall be able to obtain new and remarkable hybrids to enrich the list of varieties that already exist in our gardens. *S. appendicularis* is capable of producing astonishing results, as its beautiful leaves are much whiter beneath than those of any other plant I am acquainted with.

Bâle.

H. Christ.

Plants for the Sea-shore.

To the Editor of GARDEN AND FOREST:

Sir,—With the ever-increasing summer exodus of sea-lovers comes a demand at the different resorts, each succeeding season, for more pleasant and varied surroundings. In planting to any large extent along a shore large consideration must be had for plants which have survived and flourished among such unpropitious surroundings. In early August I made a few observations on the flora of Barnegat Peninsula, and I hope a record of them may invite attention to some of our plants which flourish in sand, and in salt-laden breezes.

Barnegat Peninsula, a strip of shifting beach, from a quarter to half a mile wide, extending from Bayhead, New Jersey, to Barnegat Inlet, is evidently of bar-formation. The long sandy barrier grew in early times, and Barnegat Bay was closed off from the ocean. It was instructive to observe the efforts of Nature to clothe the sterile landscape with vegetation. The final attempt seemed to have been made here under conditions very unfavorable to vegetal growth. The salt-grasses and salt-water sedges apparently appeared first, preparing the way for the reception of species more fastidious. Some few plants seemed peculiarly adapted to such a hard fare. The Bayberry, or Waxberry (*Myrica cerifera*), was singularly attractive. It formed dense thickets, inhabited by the mosquito and the shy cotton-tail rabbit. The leaves, when rubbed, were aromatic, and the tough stems and twigs were covered with waxy grayish white berries, which make the plant valuable for ornamental uses on the sea-shore. The

berries are gathered at times by the plain fisher-folk here, and boiled over a slow fire. The wax rises to the top, and is then skimmed off and cooled into the required form. Candles of bayberry were no infrequent commodity in rural communities during Revolutionary days.

The Poison Dogwood (*Rhus venenata*) disputes the ground with the Bayberry. Dense masses of this poisonous shrub were seen everywhere, bearing compact panicles of yellowish white unripe berries, while over the exposed sand-dunes trailed the much-dreaded Poison Ivy (*R. Toxicodendron*). The dark glossy pinnate leaves of the former turn to the most vivid and attractive hues, and are much collected and admired for their autumnal coloring. *R. venenata*, with white berries and conspicuous autumn foliage, however, is exceedingly dangerous and virulent. Notwithstanding the bad reputation of the two plants, they are important as conservatives in nature. The drifting sand is anchored; skurries of sand are prevented, and an otherwise inhospitable neighborhood is made inhabitable. Once familiar with the Sumachs, and remembering that those species only are poisonous which have white berries, one can go into the woods with impunity and collect anything herbaceous, shrubby or arborescent without fear.

Rosa lucida grew also in this sea-shore tangle, and the half-ripe hips, tinged orange, glistened in the sunlight. Associated with these species, twisted into fantastic shapes by the wintry storms, and scrawny for want of sufficient nourishment, stood the cosmopolitan Red Cedar (*Juniperus Virginiana*). Some botanists hazard the opinion that the Bermuda Cedar is only a geographical variety of the Savin of North America. It is recorded in GARDEN AND FOREST (vol. iv., p. 290) that a tract of ground in the Bermudas is covered with Bermuda Cedars of large size, springing from a dense undergrowth of Wax Myrtle or *Myrica*, identical with the species so common on our Atlantic seaboard, and of *Baccharis*, similar to, although distinct from, our seaboard species, and of *Pteris aquilina*. I found the Red Cedar on Barnegat Peninsula, with the Wax Myrtle, with *Baccharis halimifolia* and with the Bracken (*Pteris aquilina*). It seems, therefore, that the two Cedars keep the same company at least.

With this impenetrable jungle as a background, and almost buried in the salt-water sedges and grasses, the Rose Mallow (*Hibiscus Moscheutos*) covered the meadows and more elevated hummocks with brilliant pink flowers, while Golden-rods and *Sabbatias*, in close masses, occupied the foreground. The landscape, so desolate and depressing, was thus transformed into a large unkempt garden, flavored by the salt of the ocean. For those who wish to see some vegetation as a relief from the everlasting glitter of sand and water, these native settlers offer more than a hint for the proper making of a planting list.

Philadelphia, Pa.

J. W. Harshberger.

Chamæcyparis squarrosa.

To the Editor of GARDEN AND FOREST:

Sir,—Last autumn I saw in Kew Gardens a small tree with beautiful feathery, bluish gray leaves, labeled "*Chamæcyparis squarrosa*." I do not find this particular variety of *Chamæcyparis* in the books or catalogues. Is it obtainable from nurseries here? Many evergreens fail with me on exposed hills of Staten Island, and I should like to know if this one would probably prove hardy?

Staten Island.

J. M. N.

[This plant, which is an abnormal form of the well-known Japanese *Chamæcyparis obtusa*, is usually met with in nurseries, where it is now common, as *Retinospora squarrosa*. It is a rather freer-growing plant and quite as hardy as the other forms of the Japanese *Chamæcyparis* or *Retinospora*.—Ed.]

Preliminary Report on the Native Trees and Shrubs of Nebraska. By C. E. Bessey. Bulletin of the Agricultural Experiment Station of Nebraska, vol. iv., article iv.

The territory embraced in the state of Nebraska is, with reference to its native silva, one of the most interesting portions of the United States, occupying as it does a mid-continental position between the two great natural forest-regions of the east and the west. A considerable number of the species of the forests of the Atlantic seaboard extend to the eastern confines of the state, while others descending from the slopes of the Rocky Mountains reach the eastern limits of their distribution within its borders.

The list prepared by Professor Bessey contains no less than sixty-one native arborescent species, a surprisingly large number when it is remembered that, apart from the Cottonwood and Willow-lined streams, the woods are confined to the extreme eastern and the extreme western borders of the state, the central, and by far the larger part, being treeless.

From carefully prepared tables of the distribution of the different species at different elevations, and in different parts of the state, Professor Bessey reaches the conclusion that "nearly all have probably migrated to the plains from the east," and that many of them have not "done more than to get a little foothold in the extreme south-eastern counties, to which they have come from the heavy forests of Missouri. A few have doubtless crossed the Missouri River from western Iowa, although this number is evidently very small. Nearly all our trees have come up the Missouri bottoms and spread from the south-eastern corner west and north-west. Possibly a few have come up the Blue River from Kansas, but these must eventually be traced to the Missouri River bottoms at the mouth of the Kansas River." Of the plants which have traveled from the west the Buffalo Berry (*Shepherdia argentea*) appears to be the only one that has spread over the entire state; although the western Shadbush (*Amelanchier alnifolia*), a denizen of a considerable portion of western America, is found as far east as the shores of the Great Lakes. But the number of western trees and shrubs now found within the state is certainly small, considering the facilities for their transport, and, as Professor Bessey suggests, "it is singular that so few of the western plants have come down the streams, especially as prevailing winds are also from the westerly parts toward the east," and it would have appeared "much easier for the western trees to come down-stream, and with the wind, than for the Elms, Ashes, Plums, etc., to have gone up the streams against the prevailing winds." But this is explained by the supposition "that eastern conditions are slowly advancing westward; and that such climatic and other changes are slowly taking place upon the plains as favor the eastern rather than the western trees," which now appear to be slowly retreating, while eastern species are slowly pushing their way westward.

The results of Professor Bessey's investigation are of particular interest and value in the new light which they give upon the distribution of several of our trees. A comparison of his paper with the ninth volume of the *Final Reports of the Tenth Census*, in which all the information available ten years ago about the distribution of the trees of North America was supposed to have been collected, shows that the range of not less than twenty-two Nebraska trees was inaccurately given in that work. *Pinus ponderosa*, which was then believed not to grow naturally farther east than the Black Hills of Dakota, is now known, as Professor Bessey has pointed out in an earlier publication, to extend along the Niobrara River to Long Pine Creek, in Brown and Rock counties; it also occurs on the North Platte as far eastward as Deuel County and in the valley of the Loup in Valley, Greeley and Custer counties. It grows at the highest elevations in the state, ranging from over 5,000 to about 7,000 feet above the level of the ocean. Fine trees are still abundant upon the slopes and summits of rocky hills in the northern and north-western portions of the state, although the best and most accessible of the Nebraska pine has already fallen to supply the wants of the settlers.

The White Oak (*Quercus alba*), believed to have been arrested on the west by the Nodaway River, in Missouri, is now shown to reach Cass and Nemaha counties, in south-eastern Nebraska, where also occur the Red Oak (*Q. rubra*) and the Scarlet Oak (*Q. coccinea*), whose western range was not supposed to extend farther than western Iowa. The Ironwood, or Hop Hornbeam (*Ostrya Virginiana*), Professor Bessey has found in several of the eastern and northern counties, although eastern Iowa was given in the Census Report as the limit of its range westward. The fact that the Canoe Birch (*Betula papyrifera*), the Western Birch (*B. occidentalis*) and the River Birch (*B. nigra*), all occur in Nebraska, is for the first time shown in Professor Bessey's catalogue, in which are included the Butternut (*Juglans cinerea*), the Shellbark Hickory (*Hicoria ovata*), the Big Shellbark (*H. sulcata*), none of which were credited to Nebraska in the Census Report. The number of Poplars is increased by the discovery that the Aspen (*Populus tremuloides*), one of the few trees which occur on the two sides of the continent, extends as far south as Nebraska, where it has been noticed in the north-western and in the south-eastern counties, and that the narrow-leaved Rocky Mountain Poplar (*P. angustifolia*), not known before east of the Black Hill region in Dakota, really reaches Nebraska. The Papaw (*Asimina triloba*) and the Dwarf Sumach (*Rhus*

copallina) are found to grow in the extreme south-eastern part of the state, and the Little Rocky Mountain Maple (*Acer glabrum*) in Sioux County, in the north-west. The Sugar Maple (*A. barbatum*) and the Red Maple (*A. rubrum*), which were credited to eastern Nebraska in the Census Report, are now said not to grow naturally in any part of the state, although it seems probable that the second of these trees may yet be found near the borders of some of the streams which flow through the south-eastern counties into the Mississippi. Other additions to the Nebraska silva are the Witch Hazel (*Hamamelis Virginiana*), the Indian Cherry (*Rhamnus Caroliniana*), the Mountain Mahogany (*Cercocarpus parvifolius*), a widely distributed Pacific species, the Western Choke Cherry (*Prunus demissa*), the Sheepberry (*Viburnum Lentago*), and the Red Ash (*Fraxinus pubescens*).

These facts show the importance of Professor Bessey's investigation, and how much there is still to be learned about even such an apparently simple matter as the distribution of some of our most common and best-known trees. They show in particular the necessity of a careful study of the vegetation of the mid-continental region, in which are mingled plants of the east and of the west, and in which many eastern species finally disappear, and a few western species find the eastern limit of their distribution. Professor Bessey's report suggests that there is still much to be learned of the distribution of trees in the two Dakotas, in Kansas, in the Indian Territory and in Texas; and it is to be hoped that botanists living in those states, and with facilities for collecting facts about their vegetation, will follow the example of the Professor of Botany of the University of Nebraska, and make public the results of their observations.

Much remains, too, still to learn of the distribution eastward, in Idaho and Montana, of several trees of the north-west coast, and of the northern and eastern distribution of the trees of British Columbia, whose silva, in spite of the good field-work and excellent reports of Dr. Dawson and Professor Macoun, is still very imperfectly known.

Electricity in Agriculture is the title of bulletin No. 16, lately prepared by Mr. Clarence D. Warner, Meteorologist of the Massachusetts Agricultural College Experiment Station. In vol. ii., p. 442, we published the results of some experiments made at Cornell University which seemed to strengthen the opinion that electric light might be of advantage in some branches of horticulture. The experiments in Massachusetts, however, have nothing to do with light, but they are an attempt to show that electric currents passing through the ground and atmosphere have some influence on vegetation. As this is the first of a series of bulletins, it includes a brief résumé of what has been done by former experimenters, and Mr. Warner prefaces this historical sketch by the statement that the currents of sap which are carried through the rootlets, stalk and leaves of the plant depositing the elements of plant-food in their proper places are due to electricity, a theory which can hardly be considered as established. He adds, that since the plant at night is generally covered with dew it becomes a good conductor for electrical currents, which convert in their passage soil elements into plant-food and stimulate the sap to gather up the dissolved elements and carry them to their proper places. He thinks it probable, therefore, that this accounts for the fact why most plants grow more rapidly during the night than during the day.

The history given of the earlier experiments is briefly this: In 1845 plates of copper and zinc were placed in the soil where plants were growing and connected by a wire, but these efforts were fruitless of results. In 1847 Hubeck, in Germany, surrounded a field with a network of wires, and concluded that seeds germinated more rapidly and buckwheat gave larger returns. In all other cases electricity produced no result. Other men of science carried on experiments with negative results, and the abandonment of the project of applying electricity to agriculture was advised. Some years later Fichtner used a battery with effect. Parallel wires were placed in the soil, and between the wires Peas, Grass and Barley showed an increase of from thirteen to twenty-seven per cent. when compared with ordinary modes of cultivation. Fischer, of Waldheim, placed metallic supports to the number of sixty around each hectare (about two acres and a half), and at the summit of the supports were electrical accumulators in the form of crowns surmounted by teeth, which were united by metallic connection. The result appeared to increase the crop of cereals by one-half. Plates of zinc and copper, alternately placed about a hundred feet apart and connected two and two by a wire, were said to increase twofold to fourfold the production of certain garden-plants. Fischer stated that it was

proved that electricity aided in breaking up the soil constituents, and he stated that plants under this treatment matured more rapidly, were more healthy and were not affected by fungoid growth. In later experiments by Specnew, seeds were submitted to the action of an electric current, with the result of hastening germination and better-developed young plants than those grown from non-electrified seeds. The current did not affect the yield. At Kew Gardens plates of copper and zinc were placed in the soil so as to make a battery of zinc, earth and copper, with the result of increasing the crops of vegetables. Other experiments made in Pskov, in Russia, at the School of Forestry in Nancy, France, and other places, seemed to indicate that an electrical current could be profitably employed in not only garden and field crops, but that Grape-vines subjected to this treatment yielded fruit with a larger percentage of water and sugar and a lower percentage of undesirable acid.

The following experiments were made in the greenhouse at Amherst: Rectangular frames were made three feet long by two feet wide, across which were run copper wires in series of from four to nine strands, each series separated by a space of four inches, and the strands by a space of half an inch. The frames were buried in the soil so that the roots of the plants would come in contact with the wires, with the supposition that the currents of electricity passing through the wires would decompose into its constituents the plant-food near the roots and prepare it for the plants. Two electric gardens were thus prepared and furnished with a battery arranged to allow continuous currents through each series of wires. Near each electric garden was a plot prepared in the same way, except that it lacked the electrical apparatus. These gardens are designated as *A* and *B*. The soil was carefully prepared for Lettuce, and were placed where much trouble from mildew had been experienced, in order to test the effect of electricity upon the fungus. In garden *A* fifteen Lettuce-plants of the same size and vigor were set over the wires, the plants well cared for and the current kept continuous. The experiment began the 1st of January, and on the 1st of April five of the plants had died from mildew; the others were well-developed and the heads large. The largest heads were over the greatest number of wires and nearest the electrodes. It appeared that the healthiest plants as soon as the currents became feeble or ceased would be affected by mildew. On examining the roots of the plants it was found that they had grown about the wires, as if they found there the greatest amount of nourishment. The roots appeared in no way injured by the current, but rather benefited by the electrical influences. Beside this garden was one of the same dimensions, used as a check, having the same kind of soil, and treated in the same manner as the first, except that the electrical apparatus was wanting. At the close of the experiments only three plants had partially developed; two of these were nearly destroyed by mildew, and only one of these was free from disease. In the second garden, *B*, twenty plants of the same variety of Lettuce and equal size were taken and treated the same as in *A*. At the close of the test only five plants were free from mildew, seven died before they were half-grown, the rest were well-developed, but in the last part of the experiment they began to be affected. Several heads were large, the largest being over the greatest number of wires and nearest the electrodes. Near this plot were twenty other plants subjected to like conditions, but without electricity; all but one died from mildew before they were half-grown. The solitary survivor only developed partly at the close of the experiment, and was badly affected with the disease. The general result was that the plants subjected to the greatest electrical influences were hardier, healthier, larger, had better color, and were less affected by mildew than the others. Experiments were made with various Grasses, but no marked results were obtained.

Mr. Warner concludes: "It would seem that electricity is one of the agents employed by nature to aid in supplying the plant with nourishment and to stimulate its growth. To what extent plants may be subjected to electrical influences, or what strength of current is best suited, and what currents may prove detrimental to their development have not been determined, but it is desirable to continue this research until some definite information shall be gained on these points. Experiment alone can determine whether different varieties of plants differ in their capacity for enduring the action of electrical currents without injury." Mr. Warner also suggests that there may be a limit reached where electricity would completely overcome the attack of mildew and stimulate plants to a healthy and vigorous condition throughout their entire growth. We may add that if electricity is so potent in giving vigor to Lettuce it might under certain conditions give equal vigor to the mildew

and other parasitic plants. We shall look with interest to further reports on this matter, and trust that they may be carried on in the true scientific spirit, and without any attempt to establish previously formed judgments.

Notes.

At the last meeting of the Massachusetts Horticultural Society the Honorable Ephraim W. Bull, of Concord, was made an honorary member of the society. This was a well-merited, though somewhat tardy, compliment to Mr. Bull for his distinguished services as the originator of the Concord Grape.

The Executive Committee of the American Carnation Society announces that its first annual meeting will be held at the Tift House, Buffalo, New York, on the 16th of February. There will be an exhibition of flowers of the older and newer varieties, and many interesting papers on the Carnation, its diseases, its history and its cultivation.

A recent writer, in speaking of the town of Walmer, in Cape Colony, says that the Christmas decorations in its little church were the most beautiful she had ever seen. They consisted simply of magnificent blue Water-lilies and the large pure-white Arums, which the colonists unpoetically call "Pig-lilies," combined with the glossy foliage of the Arums and a few great Fern-fronds.

The fruit crop of last year in Iowa was unusually good, and the fruit-growers there feel much encouraged in spite of the suffering of this industry from severe winters in recent years. The display of apples at the meeting of the State Horticultural Society last week was remarkable for its size and quality. The society resolved to do everything in its power to make a creditable collection of Iowa fruits for the Columbian Exposition next year, and the Hon. C. L. Watrous, of Des Moines, was selected to superintend the work.

The most enthusiastic followers of the art of floral arrangement in Japan, we are told, are priests, philosophers and men of rank who have retired from public life. It has always been regarded as a fitting occupation for learned and literary men, and not at all as an effeminate accomplishment, although ladies of the aristocracy practice it as they do the other arts. Some of the virtues which are said to spring from an habitual practice of this charming art are "the religious spirit, self-denial, gentleness and forgetfulness of cares."

In a recent bulletin of the Michigan Experiment Station a record is made of the test of the value of the practice of transplanting Onion-seedlings. Seeds of several varieties were sown in a hot-bed on the 10th of April, and on the 16th the plants were transplanted to the field. Seeds of the same sort were on the same day sown in a parallel plat for comparison. The soil was rich sandy loam, and the same care was given to both tracts, with the result in every case in favor of the transplanted Onions. The variety known as Prize-taker yielded, when transplanted, 548 bushels to the acre, while those not transplanted yielded 216. The Rocca, transplanted, yielded 556 bushels against 110 when not transplanted, and Southport yielded 296 bushels against 172.

Professor Penhallow, of the McGill University, has reprinted from the *Canadian Record of Science* his papers on the *Flora of St. Helen's Island, Montreal*; and on the *Flora of Caconna, Province of Quebec*, a flora which he finds of especial interest from the fact that it contains several southern types obviously near or at the extreme northern limits of their distribution, and also many distinctively boreal species. The prevailing arboreal vegetation of Caconna Island, which in reality is not an island, but is connected with the mainland by a low neck of land not entirely submerged, even at high-water, is composed of the Black and White Spruces, the Red Pine and White Pine (this last very rare), the Larch and the *Arbor-vitæ*. The Sugar Maple, the Banksian Pine and the Aspen are common, and the Canadian Yew is often the most abundant undergrowth of the forest.

A new edition of Sir Joseph Hooker's *Himalayan Journals*, edited by G. T. Bettany, has just been added to the Minerva Library of Famous Books, published in London by Ward, Lock, Bowden & Co. This cheap edition of one of the best books of scientific travel ever written, which has long been out of print, will be a real boon to every student of science. The illustrations are printed from the original wood-cuts, and the present edition, in one volume, is identical with the first unabbreviated edition, except that some of the appendixes of lim-

ited general interest are omitted. The editor adds an interesting sketch of the author of the *Himalayan Journals*; these were published in 1854, and the author, now the most distinguished English botanist, is very nearly at the end of his task of describing the plants of India, for which he fitted himself in the long and dangerous journeys of which these *Journals* are the record.

The eleventh part, the last to reach us, of the American edition of the sumptuous *Lindenia*, or *Iconography of Orchids*, conducted by the Messrs. Linden, of Brussels, with the assistance of Em. Rodigas and R. A. Rolfe, contains portraits of *Cattleya* × *Hardyana*, var. *Laversinensis*, a supposed natural hybrid between *C. aurea* and a variety of *C. gigas*, imported several years ago from New Granada. The flowers are fragrant, with light rosy mauve sepals and petals, and a deeper-colored lip. Several forms of what are doubtless the same hybrid, differing slightly in the color and markings of the flowers, have appeared in different collections. The one which Monsieur Linden has selected for his beautiful plate first flowered in Baron Rothschild's gardens at Laversine, in France. The other figures in the number are of *Rodriguezia pubescens*, *Ærides suavissimum*, and *Disa grandiflora*, the magnificent terrestrial Orchid from South Africa, a now well-known plant, but hardly surpassed in the beauty and showiness of its flowers by any other Orchid. *Lindenia* is a store-house of information which cultivators of Orchids will find invaluable. The illustrations are not surpassed by those of any other work of the same character and scope.

In a paper prepared for the American Pomological Society, Professor W. F. Massey calls attention to the peculiar advantages of the mountain-region between the Blue Ridge and the Alleghany Ridges in western North Carolina for the cultivation of apples: "The wonderful capacity of these elevated valleys and mountain-slopes for the production of apples of a size, beauty and flavor unknown in the same varieties grown elsewhere, is rapidly coming to be acknowledged since the great displays made by this section at the Centennial Exposition and at the meeting of this society in Baltimore in 1877. The trees are larger, more vigorous and longer-lived than in most other places. In one orchard, in Haywood County, there are more than 100 trees averaging nine feet in circumference of trunk. Trees of this size are common in most of the mountain counties, and they are in the most luxuriant health. In the elevated valleys about Waynesville, in Haywood County, the Yellow Newtown Pippin grows to the same perfection as on the mountain-sides in Albemarle County, Virginia, where it is known as the Albemarle Pippin. In the summer of 1890 there was scarcely any fruit in all the country east of the Mississippi River and in all other parts of this state. In these mountains not only were the Apple-trees loaded with fruit, but Peach-trees were breaking down with their crop. That there are extensive belts on these mountain-sides where early autumnal and late vernal frosts are unknown, is a well-attested fact, and this renders the culture of fruit there more certain than in any other section of the eastern states."

In the Government report of crops for last year there are some valuable lessons as to the prices of farm-products. The crops were almost without exception large, and under such circumstances prices are always reduced. Singularly enough this decline in prices is often greater in proportion than the increase in production, so that the surplus depresses the total value of the crop. For example, in 1890 the supply of potatoes per capita was smaller than it had been for many years, and therefore the price per bushel ranged very high; nevertheless the inferior quality in most of the districts where production is the largest prevented farmers from securing the advantages of these high prices. Last year the crop was enormous and the acreage planted large, so that there has been a heavy decline in prices. This decline has been so serious that while the country produced 100,000,000 bushels more than it did the year before, the aggregate value of the crop is less than that of 1890 by \$20,000,000. On the other hand, the wheat crop was twenty per cent. greater in 1891 than in 1890, and yet the price per bushel slightly exceeds that of a year ago. The reason for this is that, although the crop is largely beyond the requirements of home consumption, there is an extraordinary demand for it abroad which has sustained the prices. The aggregate value of the present wheat crop is about \$179,000,000 greater than that of last year, and the enormous corn crop, in spite of the fact that it is twenty per cent. less per bushel than it was last year, is worth to farmers at December prices about \$80,000,000 more than the crop of 1890.

The January Thaw.

WITH hardly frost enough preceding to excuse it, the January thaw made its appearance early in the new year to add its terrors of melting snow and heavy atmosphere to the already unhealthy season.

This freak of nature is detestable enough in towns, where there is some slight mitigation of its evils by the intervention of sidewalks, with their attendant shovels and brooms. Though the dripping roofs, the reeking gutters, the slippery pavements, the muddy crossings, make the pedestrian's career precarious enough, the most disagreeable of city thaws does not begin to interfere with domestic comfort, or impede locomotion, as a similar infliction does in the rural districts, where roads and paths become well-nigh impassable with mud and slush.

That part of this annoyance might be avoided by proper care on the part of the road commissioners is well known, but there is always a reluctance shown by towns to make the proper appropriations for the maintenance of the highways, which show all their defects in a thaw.

If all the low portions of these thoroughfares could be properly drained, and a good bed of stones provided beneath, the surface moisture would soon drain off, and leave a firm and reasonably dry surface for travel. The saving of expense in the long run, in the wear and tear of vehicles, and in the time of individuals, now wasted in slow endeavors to get from place to place through sloughs of mud, would well repay a large expenditure to properly prepare the roads in the beginning; but here the penny-wise and pound-foolish policy is apt to prevail, to the trial of horse-flesh and patience.

If any one will remark the difference between a gravelly road and a low undrained stretch of highway, he will promptly recognize the service that a porous understratum renders to the passenger. So soon as the sun thaws the snow the former gives a firm surface for travel, while the latter grows steadily worse as the dissolving snow-heaps pour their waters into the tank formed by the impervious soil. In the one case drying can only be effected by

evaporation, while in the other the moisture steals away by a million underground channels, which can be prepared for it by a foundation of broken stone. With the long-suffering of American communities trained to a make-shift policy, we put up with a state of things that was prevalent in England a hundred years ago, but which has been done away with there on the great lines of travel, as it could easily be done away with here by a resolute effort on the part of our townspeople at their annual meeting, when a different policy of managing the roads should be urged and generously sustained.

It is at this season of melting snow and lowering heavens that facilities of travel are most essential to the dweller in the rural districts, compelled as he is to the contemplation of a melancholy landscape, for if the country can ever be a sorry sight it is on one of those bedraggled days when the heavy gray sky comes down upon the sodden earth and envelops it in a dripping mantle. The picturesqueness of a veiled distance, apparent enough through a summer rain, has vanished, and only near objects are visible.

Big tear-drops hang from every joint of the vines on a veranda, as if the skeleton creepers were bemoaning this pitiable sight. Whatever is not mud-color or white in the landscape, is black. The trees have gone into mourning, the fence-rails are plunged in gloom. Near houses look dingy; more distant ones, if visible, shiver forlornly under their chilly trees. The evergreens themselves show a shabby winter raiment of rusty green, specked with brown. Not a snow-bird or a sparrow ventures abroad.

A heavy wagon at long intervals struggles through the mud, or a be-mired foot-passenger picks his dreary way among the puddles and stiff ridges left by the snow-plow in its travels. The very dogs and cats are housed, and cling to the warm fireside rather than venture abroad out-of-doors.

This is winter in undress, without his ermine robe and glittering crown of icicles, and a disreputable old monarch he shows himself when not in gala attire. To those who go forth to face him he gives but a chilling greeting. His sleety breath, his freezing mists, are enough to deter the stoutest-hearted member of the Appalachian Club. There is stimulus in a brisk snow-storm but a winter fog disheartens even the brave, who fear its "grip" even more than its cold embrace. Tremble as we may at nipping cold and icy blasts, we brace ourselves to meet them, and the blood flows more freely for the effort. It is the inert depression of the motionless mist that induces gloom, and against this man needs all his resolution.

Here must the mind act upon the shivering frame, and rouse it to combat with the outside enemy. For it is during these winter imprisonments that the dweller in the country finds time for study and reflection, for the free exercise of thought and the construction of plans for the future. Those influences which tend to throw the mind back upon itself are the real enhancers of intellectual growth. In the roar and hum of contact with human life, in the restless resounding of calls to active duty, the soul fails to catch the note of its own bell, which only in silence and solitude may vibrate with a clear tone.

So sensitive is the intelligence that it more often renders an echo than an original note, which gives us a consolation even for the limitation of facilities for locomotion, and even leads us to be grateful for those natural causes which, against our will, conspire to seclude us for a while to the benefit of our individual growth and to the strengthening of our own mental vibration.

Thus even a January thaw, with its neglected country roads, which prevent travel and interruptions, may serve as a needed refreshment to a jaded intellect by driving it to the true sources of development, meditation and recollection, for it is not so much bodily activity, nor the contact with others, that inspires original thought, as that communing with one's own soul in the stillness, from which the greatest results have ever been born.

The Aspect of Trees in Winter.

THE genuine lover of trees finds it difficult to decide at what season they are the most attractive. Even in the dreariest period of the year they display beauties which are hidden by the luxuriant foliage of summer, and it is only by a study of their naked framework that we can discern the reason for their most characteristic appearances at other seasons. One of the most distinctive aspects of a tree in summer is found in the way in which the masses of its foliage break into lights and shadows. A glance at an Oak or Chestnut in the winter will show that the trunks of these trees divide into a comparatively small number of large branches, which leave deep irregular openings for dark shadows in the foliage in strong contrast with the light on well-defined masses. The smoother surface of a vigorous young Sugar Maple in leaf shows smaller and more numerous tracts of light and shade, and this is caused, as can be readily seen in winter, by the more numerous and slender branches of nearly equal length which radiate at a uniform angle from the central stem. Again, the appearance of trees in summer is influenced greatly by the way in which the masses of foliage sway in the wind, and this movement depends on the length and flexibility of the branches. The skeleton of the tree, therefore, not only determines its contour, but it is this structure rather than the mantle of leaves which determines the fundamental expression of the tree, whether of majesty or grace, of cheerfulness or gloom.

We have often invited attention to the marvels of color and texture displayed by the bark of various trees, to the soft tints and varied grace of the spray of different species, and to the delicate tracery of their interlacing branches when seen against the sky. All these can best be seen in winter, and perhaps we are more attracted by beauty of this sort at a season when the fields have no verdure, and the waysides no flowers, to withdraw our attention. The more we study them the more we shall discover to excite admiration, and we may find something characteristic even in the smallest twig or the dead leaf which still clings to it. Gilpin long ago, in his delightful book on forest-scenery, showed that the English Oak develops naturally into its wide-spreading form because of the almost horizontal divergence of the young branches from the stem, and that this same rectangular structure which gives the tree its massive and sturdy appearance can be seen throughout the entire system of branches to the remotest spray. The picture of the extremity of a Black Oak-branch (*Quercus tinctoria*), on page 55, from one of the series of remarkable photographs with which Dr. Rollins has kindly favored us, might stand by itself as the type or emblem of a northern winter; and the persistency with which the dead leaves have clung, in spite of bitter winds, is a convincing proof of the tough and enduring fibre of the tree. On an Oak of this species which stands alone on some wind-swept upland many of the leaves by midwinter are torn like old banners, and their strong stems are twisted into bundles of yellow cords. When the leaves are finally swept away the ends of these fibres still cling to the spray and present a weird, blossom-like appearance, which reminds one of Witch Hazel flowers. All these will be seen beautifully brought out in the picture, together with the perfect form of the buds and the close texture of the bark.

FROM an article which appeared in the *Minneapolis Tribune*, of January 19th, it would seem that the leading opposers of the proposed forest-reservation in northern Minnesota have been converted from enemies into friends and have enlisted as promoters of the movement. The Duluth Chamber of Commerce stood in the front of the fight against the reservation, which, in the eyes of the merchants of that town, seemed to threaten its business by crippling the railways and withholding its supplies of lumber and minerals. Mr. Thompson, the Secretary of the

Chamber, was, therefore, sent to the annual meeting of the State Forestry Association, at Minneapolis, to make protest against the movement, but when he learned that instead of withholding the timber from use it was proposed to secure a constant lumber-supply, and that the forests, when protected from fire and larceny and skillfully managed, would be much more productive than it is under the present lack of supervision, Mr. Thompson himself joined the association, and was made a member of the executive committee, which is laboring to induce the President to make the proclamation withdrawing the timber-lands from sale and entry. If this reservation is established and placed under judicious control, it will doubtless prove a lasting benefit in many ways to the people of the United States.

Is Grafting a Devitalizing Process?—II.

WE herewith present the conclusion of the paper read by Professor L. H. Bailey before the Peninsula Horticultural Society. In the first part of the paper it was contended (1) that any number of examples of unsuccessful grafting do not prove that the practice itself is harmful, and (2) that it is a fallacy to assume that grafting is unnatural, and therefore pernicious.

3. It is said that own-rooted plants are better than foster-rooted ones. This is merely an assumption, and yet it has been held with dogmatic positiveness by many writers. If mere unnaturalness, that is, rarity or lack of occurrence in nature, is no proof of perniciousness, then this statement admits of argument just as much as any other proposition. And surely at this day we should test such statements by direct evidence rather than by a priori convictions. And here I will repeat that the citation of any number of instances of the ill effects of graft is no proof that own-rooted plants are necessarily better, if there should still remain cases in which no injurious effects follow. Now, if it is true that "own-rooted things are always infinitely better, healthier and longer-lived" than foster-rooted plants, and if "grafted plants of all kinds are open to all sorts of accidents and disaster," then the proposition must admit of most abundant proof. I will analyze the subject by discussing the following questions: *a.* Is the union always imperfect? *b.* Are grafted plants less virile than own-rooted ones? Are they shorter-lived?

a. It is well known that the physical union between cion and stock is often imperfect, and remains a point of weakness throughout the life of the plant. But this is not always true. There are scores of plants which make perfect physical unions with other plants of their own species, or even with other species, and it follows that these alone are the plants which should be grafted. The very strongest proof which can be adduced that the union may be physically perfect can be seen in the micro-photograph of an Apple-graft, published two years ago in the *American Garden* (xi., 65), by Professor C. S. Crandall. The cells are knit together so completely that it is impossible to determine the exact line of union. I have in my possession a number of the micro-photographs, taken by Mr. Crandall, which show the same condition. (These were exhibited at the convention.) Mr. Crandall also figures, on the same page, a microscopic section of an Apple-graft in which the union is very poor, but this graft was made in a different manner from the other, and presents another proof that the operation should be suited to the subject.

These were grafts made upon nursery stock, and it would appear that if the union were good at the expiration of the first year it would remain good throughout the life of the plant. In order to test this point, I procured two Apple-trees, fifteen years old and over six inches in diameter, which had been grafted at the surface of the ground in the nursery. In the presence of two critical observers I split the trunks into many pieces, but no mark whatever could be found of the old union. The grain was perfectly straight and bright through the crown. I am the more willing to cite this case because I had fully expected to find a decayed or dead portion, or contorted grain, at the point of union; but every internal evidence of a graft had disappeared.

So far as the strength of a good union is concerned, all fruit-growers know that trees rarely break where they are grafted. There is an old seedling orchard upon my father's farm into which many grafts had been set. I have myself set many hundreds of these grafts in the tops of the trees, often far out

on large limbs, and in the immediate neighborhood I have set many thousands under similar conditions; and yet, with all the breaking of the trees by ice, storms and loads of fruit, I have never known a well-established union to break away. And I have had the same experience with Cherries and Pears. I have lately tested the strength of the union in a different way. A few days ago I cut two "stubs" from an old and rather weak Apple-tree, which had been cleft-grafted in the spring of 1889. These stubs were sawed up into cross-sections less than an inch thick, and each section, therefore, had a portion of foreign wood grown into either side of it. These sections were now placed on a furnace and kept very hot for two days, in order to determine how they would check in seasoning, for it is evident that the checks occur at the weakest points. But in no case was there a check in the amalgamated tissue, showing that it was really an element of physical strength to the plant. A similar test was made with yearling Mulberry-grafts, and with similar results; and this case is particularly interesting, because there were three species intergrafted—the common Russian Mulberry, *Morus rubra* and *M. Japonica*.

From all these considerations it is evident that, admitting that hundreds of poor unions occur, there is no necessary reason why a graft should be a point of physical weakness, and that the statement that "grafted plants of all kinds are open to all sorts of accidents and disaster" is not true.

6. Are grafted plants less virile—that is, less strong, vigorous or hardy—than others? It is evident that a poor union or an uncongenial stock will make the resulting plant weak, and this is a further proof that indiscriminate grafting is to be discouraged. But these facts do not prove the affirmative of my question. There are two ways of approaching the general question—by philosophical considerations and by direct evidence. It is held by many persons that any asexual propagation is in the end devitalizing, since the legitimate method of propagation is by means of seeds. And this notion appears to have found confirmation in the conclusions of Darwin and his followers that the ultimate function of sex is to revitalize and strengthen the offspring by the union of the characters or powers of two parents; for if the expensive sexual propagation invigorates the type asexual propagation would seem to weaken it. It does not follow, however, that because sexual reproduction is good, asexual increase is bad, but rather that the one is, as a rule, better than the other, without saying that the other is injurious. We are not surprised to find, therefore, that some plants have been asexually propagated for centuries with apparently no decrease of vitality, although this fact does not prove that the plant might not have positively increased in virility if sexual propagation had been employed. The presumption is always in favor of sexual reproduction, a point which I suppose will be admitted by every one. And right here is where grafting has an enormous theoretical advantage over cutting or any other asexual multiplication; the root of the graft springs from sexual reproduction, for it is a seedling, and if the union is physically perfect—as I have shown is frequently the case—there is reason to suppose that grafting between consanguineous plants is better than propagating by cuttings or layers. In other words, grafting is really sexual multiplication, and if seeds have any advantage over buds in forming the foundation of a plant, graftage is a more perfect method than any other artificial practice. It is, in fact, the nearest approach to direct sexual reproduction, and when seeds cannot be relied upon wholly, as they cannot for the reproduction of many garden varieties, it is the ideal practice, always provided, of course, that it is properly done between congenial subjects. It is not to be expected that the practice is adapted to all plants, any more than is the making of cuttings of leaves or of stems, but this fact cannot be held to invalidate the system.

It has been said in evidence that grafting is a devitalizing, or at least a disturbing, process, that grafted plants lose the power of independent propagation. Mr. Burbidge writes that "any plant once grafted becomes exceedingly difficult of increase except by grafting." I have never known a case in which this is true. We are now forcing wood from both budded and cutting-grown Roses, and cuttings grow equally well from both. All our fruits grow just as readily from seeds from grafted as from seedling trees, and I have never heard of a well-authenticated case of a plant which grows readily from cuttings becoming any more difficult to root after having been grafted.

But is there direct evidence to show that "grafting is always a makeshift"; that it is a "toy game"; that "grafted plants of all kinds are open to all sorts of accidents and disaster"; that "own-rooted things are in all ways infinitely better, healthier and longer-lived"? These statements allow of no exceptions;

they are universal and iron-bound. If the question were to be fully met, we should need to discuss the whole art of grafting in all its details, but if we can find one well-authenticated case in which a grafted plant is as strong, as hardy, as vigorous, as productive and as long-lived as seedlings or as cutting-plants, we shall have established the fact that the operation is not necessarily pernicious, and shall have created the presumption that other cases must exist.

Some forty years ago my father took Apple-seeds from his old home in Vermont and planted them in Michigan. Upon my earliest recollection the resulting orchard was composed of some hundred or more lusty trees, but as most of the fruit was poor or indifferent, it was decided to top-graft the trees. This grafting was done in the most desultory manner, some trees being grafted piecemeal, with some of the original branches allowed to remain permanently, while others were entirely changed over at once; and a few of them had been grafted on the trunk about three or four feet high when they were as large as a broomstick, the whole top having been cut off when the operation was performed. A few trees which chanced to bear tolerable fruit, scattered here and there through the orchard, were not grafted. The orchard offers, therefore, an excellent test in this matter. Many of the trees in this old orchard have died from undeterminable causes, and it was an interesting fact that fully half, and I think even more, of the deaths have been seedling trees which were for many years just as vigorous in every way as the grafted trees; and of the trees that remain the grafted specimens are in every way as vigorous, hardy and productive as the others. And some of these trees have two tops, one of which was grafted shoulder-high in the early days, and the other grafted into the resulting top many years later. And those trees which contained both original branches and grafted ones in the same top show similar results; the foreign branches are in every way as vigorous, virile and productive as the others, and they are proving to be just as long-lived. Here, then, is a positive experiment compassed by the life-time of one man, for my father is still living, which shows that own-rooted trees are not always "infinitely better, healthier and longer-lived" than grafted plants. And, furthermore, cases like this are by no means rare, nor are they confined to fruit-trees. In the case of Peaches I have had a similar experience. The first orchard upon my father's place was composed entirely of seedlings, yet the trees were no longer-lived than budded trees, and they were attacked just as seriously by the yellows. And in this connection I will cite the fact that the old seedling orchards which still remain to us about the country are much more uneven, contain more dead trees or vacant places, than the commercial orchards of even the same age. This is due, as I have pointed out upon another occasion (On the Longevity of Apple-trees, before Kansas Horticultural Society, 1890), to the struggle for existence in the old orchards by which the weak trees have disappeared, while the grafted orchards, being made up of selected varieties of known virility and hardiness, have remained more nearly intact. And if the seedling orchards have suffered more than the grafted ones, it must be because they have had more weak spots.

I contend, also, that the universal favor in which grafting is held in America is a strong presumption in its favor. We differ among ourselves as to the best methods of performing the operation, but I have never heard an intelligent American condemn the system as necessarily bad or wrong. In 1890 there were growing in the United States nurseries 240,570-666 Apple-trees, 88,494,367 Plum-trees, 77,223,402 Pear-trees, and 49,887,894 Peach-trees, with enough other species to make the total of fruit-trees 518,016,612. All of these will go as grafted or budded trees to the consumer, and he will accept none other. It is true that half of them may die before they reach bearing age from various causes, but grafting itself plays a small part in the failure, as may be seen in the case of Grapes and small fruits, which outnumber the tree-fruits in nursery stock, and of which less than one-half probably reach maturity, and yet these are all cutting-grown plants. It is in nineteen cases out of twenty the carelessness of the grower which brings failure.

I have drawn my arguments and illustrations from fruit-trees, because I have had a more extended familiarity with them, and it has been my desire to determine if grafting is of itself necessarily pernicious, rather than to discover its merits in specific cases. I am sure that others can corroborate my conclusions on various ornamental plants, and I could myself cite many instances.

It is impossible, if one considers the facts broadly and candidly, to arrive at any other conclusion than this: Grafting is not suited to all plants, but in those to which it is adapted—and they are many—it is not a devitalizing process.

Notes on the Mid-winter Vegetation of Central Florida.

A BRIEF visit to central Florida, extending over the last fortnight of December and the early days of January, afforded an opportunity for making some general studies of the vegetation there. At first sight, perhaps, the most striking characteristic of the flora as a whole is the sharp line of demarcation between the species occupying different, but adjacent stations, corresponding mainly to difference in soil. The two main divisions of this kind are termed Pine-land or barrens, and hammock. On the Pine-land two species only are predominant—the Long-leaved Pine and the Saw Palmetto. The former are usually of small size, perhaps fifty feet in height, with trunks a foot in diameter, rather sparsely scattered as to numbers, the trunks usually unfurnished with branches except at the upper part, while the undergrowth is almost everywhere the Saw Palmetto, often abundant enough to nearly cover the soil, which seems to consist of nothing but white sand. Whatever may be the appearance of these Pine-lands at other seasons, they are at midwinter sufficiently barren and dreary.

In marked contrast to this is the hammock. Here we find a vegetation suggestive of tropical luxuriance. There are many kinds of trees, some of them attaining a large size, with a dense and tangled undergrowth made up of a wide range of species. Often the vegetation of the hammock rises up like a wall on the border of the Pine-land, with little or no intermingling of the characteristic species of the two floras. In the main the hammock appears to follow or is in the neighborhood of the water-courses, or in the vicinity of lakes, and the soil, though still apparently made up almost entirely of white sand, is far richer in plant-food than that of the barrens; but not infrequently in the midst of the rich hammock appear small patches of Pine-land, called locally Pine-pockets, sharply set off from the surrounding hammock, and possessing all the characteristics of the wide expanses of Pine-barrens, which occupy too much of the surface of the region. However, there are Pine-lands of better quality, where the trees grow to a larger size, and the Palmetto becomes a less distinctive feature of the undergrowth.

Still another division of the general flora is seen in the wet swamps found on the borders of lakes or along the streams. Here the appearance of the vegetation and the representative species are as markedly different from the two previous divisions as these are from each other. The characteristic tree is the Bald Cypress, in form not at all like the typical conifer, the gray trunks quite unfurnished, and the deciduous portions of the broad flat top now turned to a rich soft brown. In inundated swamps there is always an abundant development of those most remarkable root-growths, the knees, sometimes perhaps a hundred pertaining to a single tree, rising in height from one to five feet or more, and usually in the form of sharp narrow cones, and often separated from each other and from the parent tree by intervening spaces of water.

The prevailing color of vegetation everywhere at this season is a dull soft gray; this would hardly be expected in a country where so many evergreens abound like the Magnolias and Live Oaks, to say nothing of the Palms. But vegetation is for the most part now at rest, for here in this sunny clime they have as distinctive a winter, although the thermometer may not indicate it, as in more northern regions. The foliage of the Live Oak and other broad-leaved evergreens is now mature, and has lost the brighter green of the growing season; while the soft gray long moss, draping almost everything in wonderful abundance, of itself gives tone and color to the landscape.

While the northern visitor meets with numerous species of marked interest, perhaps the Palms at the outset take the highest rank. Of the eight unquestioned species found in the state, only four occur in central Florida, and of these only two are common, the Saw Palmetto and Cabbage Palmetto. Small plants of these two species, when seen at a distance, appear to the unpracticed eye much alike; but the always strongly curved midveins of the leaf-blade of the latter are never seen in the former. The Cabbage Palmetto, as seen here in mature and more perfect specimens, is really a stately and beautiful tree, a worthy representative of the noble family to which it belongs. Its favorite place of growth is the banks of streams or lakes if not too wet, sometimes forming groves exclusive of other trees; but it also occurs in the hammock scattered here and there in greater or less abundance.

In making excursions through the hammock one does not overlook the fact that many northern species here find a home. Sabal Palmetto and *Liriodendron tulipifera* appear as friendly

neighbors, the latter often reaching fine proportions, with trunks three feet in diameter. *Magnolia grandiflora* and *Acer rubrum* are within hailing distance, the ripened foliage of the latter still clinging to the branches, but the faded color suggesting an ill attempt at reproducing the scarlet hues which helped to make the woodlands of the north brilliant three months ago. On tree-trunks, quite strangers to its northern kindred, the Virginia Creeper finds support. The plants look dwarfed, as though not quite at home, but the still unfallen leaves, unlike those of the Maple, have taken on a brilliant color. Altogether, a considerable number of northern plants are seen, but southern species, as Magnolias and Palms, predominate, and give to the woodlands, as a whole, a distinctive sub-tropical aspect.

At Christmas-time one finds in an hour's ramble along the highways and on the borders of woods perhaps a dozen species in bloom. In this enumeration the straggling and belated flowers of several Asters and Golden-rods, now long past their prime, are not included. With especial interest one comes upon the Common Blue Violet, now fully in bloom, and growing in considerable abundance in damp places; but the plants are less vigorous and the flowers smaller and paler than at the north. On the sandy margins of Lake Charm we find the odd little *Utricularia subulata*, the single bright yellow flower in size quite out of proportion to the slender leafless stem. On comparatively dry soil are pretty clumps of *Pinguicula pumila*, the light purple or almost white flowers at first sight appearing more like Primulas than Butterworts. *Gelsemium sempervirens*, abundant everywhere on the margin of moist woods, is just coming into bloom, while near a group of Palmettos some broad white cymes of the Common Elder are fully expanded. Close down on the sand, in little patches, are the tiny creeping stems of *Oldenlandia rotundifolia*, the bright white flowers of relative large size. It is very pretty, but has little resemblance to its near relative, the Bluets of the north. These species, and perhaps a few others now in bloom, are here the real harbingers of spring.

But there are still to be seen interesting remnants of the autumnal flora. In this category ought, probably, to be placed the beautiful *Coreopsis aurea*; but whether of late autumn or early spring, it just now enlivens everywhere the sides of ditches and the borders of swamps with its warm golden color. Now almost out of bloom and coming into fruit is the shrubby composite, *Baccharis glomeruliflora*; it is six or eight feet in height, with numerous heads of inconspicuous flowers, but the upper branches are more showy with the dense tufts of white pappus, in beautiful contrast with the coriaceous evergreen leaves. This, however, is true only of the female plants, the species being strictly dioecious, and the pappus of the male plants but little developed.

Altogether, with expectations formed by long familiarity with glowing accounts of Florida as a region of perpetual bloom, one may find the vegetation at midwinter a little disappointing as to the abundance of flowers, but he cannot regard it, on the whole, as otherwise than sufficiently entertaining and instructive.

New or Little-known Plants.

Smilax Pseudo-China.

THE great genus *Smilax*, represented in the tropics, and in the north temperate regions of the two hemispheres by some two hundred species, extends north in eastern America to beyond the northern limits of the United States. The species are herbaceous, or are stout woody climbers, and the genus is principally valuable, economically, for China-root, a drug once much more esteemed than it is at present, derived from the root of *Smilax China*, a thorny climber of eastern India, China and Japan, and for sarsaparilla, the root of various species found in different countries of tropical America. Botanists have distinguished fourteen or fifteen species in the United States, but these are still very imperfectly known, and in the flora of the eastern states there is no group of plants of whose life-history there is more to be learned. But as the different species are scattered over a wide extent of country they will never, probably, be thoroughly understood until all the forms are gathered together and cultivated side by side—a difficult undertaking, as many of the species are peculiar to the extreme southern states, and are not hardy in that part of the country where experimental gardens are usually found. The difficulty of

studying the plants of this genus in a satisfactory manner is also increased by the fact that the staminate and pistillate flowers are often produced on different plants, although the entire separation of the sexes does not appear to be as common as has been usually supposed.

The coast region from southern New Jersey to Florida is the home of the greatest number of species in the United States, although several extend into southern New England, and two of them far north. Of the value of the North American species of *Smilax* as garden-plants as little is

a less vigorous plant than the Greenbrier, with pale ovate leaves, glaucous on the lower surface and slenderer, and less terribly armed branches, and *Smilax Pseudo-China*.

This last (see Fig. 10), which is an old inhabitant of the Arboretum, where it has become thoroughly established, is a vigorous plant, rather common in dry or sandy soil in all the region from New Jersey to Missouri and Florida. It produces from tuberous root-stocks stout branches, which climb five or six feet high, and which are sometimes unarmed, and sometimes furnished with occasional weak

Fig. 10.—*Smilax Pseudo-China*.—See page 52.

known as of their life-history. Some of the species grow rampantly and produce handsome foliage and brilliant black or bright red fruit, and there are many places in the garden where they can be used with good effect. Three species only are well established in the Arboretum; these are the familiar Greenbrier or Bullbrier (*Smilax rotundifolia*), in all the northern states an inhabitant of moist thickets, which it often makes impenetrable by its climbing well-armed branches clothed with lustrous, broad, heart-shaped leaves—this is one of the most beautiful plants of its class, and one of the best to use to protect a boundary plantation from intrusion; the glaucous *Smilax* (*S. glauca*),

prickles. The leaves are deciduous, ovate, heart-shaped, sharp-pointed, three or four inches long, two or three inches broad, prominently five-ribbed, dark green on the upper and paler on the lower surface; they are borne on slender petioles from a half to two-thirds of an inch long, or two or three times shorter than the flattened stems of the flower-heads. The flowers, like those of the other members of the genus, are greenish yellow, and individually quite inconspicuous; they are described as diœcious, but a plant in the Arboretum, where for a long time there was only one individual, has produced crops of fruit every year, and the seeds of this fruit have produced plants. The fruit

is black, a third of an inch in diameter, and rather showy, although it is the beauty of the foliage, and not that of the flowers or fruit, which makes *Smilax Pseudo-China* a good garden-plant.

Foreign Correspondence.

London Letter.

THE INTRODUCTION OF EXOTIC PLANTS INTO EUROPEAN GARDENS.—A paper on this subject was read in September, last year, by Dr. Gregor Kraus before the Naturalists' Society of Halle. The author has been to considerable pains in collecting information, and his paper has proved of sufficient interest to be reprinted. He divides the subject into six periods, as follows: The first period was the middle of the sixteenth century, when Hyacinths, Tulips, Lilies and similar bulbs were cultivated in Augsburg. It was not until nearly a hundred years after that they were taken up by the Dutch. The second period was marked by the introduction of North American trees, chiefly into France, the garden of Monsieur Robin, in Paris, then being famous for its collection of these plants. The third period began in the middle of the seventeenth century, when the Dutch introduced many plants from south Africa, and cultivated them in the Botanical Gardens at Leyden and Amsterdam.

A catalogue of the Cape plants in the former garden was published in 1668. Leyden is said to have possessed the first recorded glass house for plants; this was in 1599. During the latter part of the seventeenth century the formal style of gardening known as the French style was discarded by many in favor of the English style, the latter admitting of the use of a greater variety of plants than was possible in a typical French garden. The fourth period opens at the beginning of the eighteenth century and continued till near its close. During this time large numbers of hardy trees and shrubs were introduced from temperate regions. Then follows the Australian or fifth period, when the interesting vegetation of the Australian continent attracted the attention of horticulturists. The bulk of the plants were introduced by Kew and the English nurserymen. Dr. Kraus found the part played by the English in the introduction of exotic plants far too great and important to be included with that of the rest of Europe. He therefore decided to deal with it separately in a second paper. The Australian and Cape plants introduced into England did not receive much attention from the Continental horticulturists until the beginning of the present century. The sixth period is that of the last ninety years, and is remarkable for the enormous number of tropical plants introduced. It was not until Mr. Ward invented his little portable greenhouses, Wardian cases, that much success was attained. The chief cause of success, however, has been the shortening of the journey by the improvements made in ships, the modern "ocean greyhounds" bringing the plants often in less than one-fourth of the time it took half a century ago. Previous to this period the introduction of living plants was left almost entirely to botanical gardens and a few wealthy amateurs. But nurserymen now saw their opportunity, and dispatched collectors in the interests of trade.

Of the modern mania for Orchids, as he terms it, Dr. Kraus says very little. Orchid madness, he states, is almost peculiar to the English, who import plants by the ship-load and dispose of them by large auction sales. The plants thus eventually find their way all over Europe. Special houses even are devoted to single genera (he might have said species!) and some of the varieties are sold for enormous sums.

The taste for all kinds of exotic plants and their cultivation have, he says, not only proved a source of wealth, by adding an important industry, but it has also been of great value scientifically, many departments of botany and even chemistry having made considerable progress by means of the living material being available for study and research.

The history of exotic gardening in England, at any rate, differs in some important particulars from that given above. We therefore look forward with interest to the publication of Dr. Kraus' second paper.

Included in the first paper are various statistics showing the number of exotic plants cultivated in different periods, and, for comparison, of the number cultivated in the three largest representative collections in Europe now, namely, those at Kew, Berlin and St. Petersburg. The figures from Kew, which I know are approximately accurate, are herewith given, since they will, no doubt, prove interesting to your readers:

The number of species and varieties of the various classes of cultivated plants at Kew in 1891 are as follows: Orchids, 1,500; Ferns and Lycopods, 1,500; hardy Ferns and Lycopods, 800; Palms, 500; Cycads, 94; Pandanads, 36; Cyclanths, 19; Aroids, 313; Scitaminæ, 228; Bamboos, 71; succulents, 1,350; miscellaneous stove-plants, 2,756; miscellaneous greenhouse-plants, 3,021; bulbs and Oxalis (indoor), 700; herbaceous plants, Dicots, 2,000; herbaceous Monocots, 1,000; alpine, 1,000; hardy trees and shrubs, 3,000. Total, 19,800.

Roughly, therefore, we may say that Kew has in cultivation 20,000 plants, all, except a very small fraction, exotics. The figures here given do not include such plants as garden varieties of Pelargoniums, Narcissus, Caladium, Roses, etc.

The history of Kew and its collection will shortly be the subject of a special number of the *Kew Bulletin*. Last year was the jubilee of the nationalization of the gardens, although a portion of them existed as a private garden fully 200 years ago. This, with the house adjoining, was acquired by the son of George II. in 1730, and soon became famous for its botanical collection, William Aiton, a pupil of Philip Miller, being placed in charge of it. In 1841 it was handed over to the public by the present Queen, and Sir William Hooker was appointed Director. The collection now comprises almost every species of plant known to be in cultivation.

HORTICULTURAL TRAINING.—This subject is now being discussed with some warmth in the London gardening papers. The county councils for the home counties have decided to devote a certain sum annually to the work of teaching the art of gardening by means of lectures. Lecturers have been appointed for each county, and the work of teaching, by means of talk and magic-lantern illustrations, has begun. Some competent judges have questioned the wisdom of this kind of thing, no less an authority than the Director of Kew, Mr. Thiselton-Dyer, having stated publicly that "the cultivation of plants is an art which can only be acquired by practice, and therefore, it appears to me, cannot be taught in the lecture-room any more than painting or shoemaking. I know of no royal or theoretical road to the acquisition of a competent or even useful knowledge of the gardener's art except by beginning at the bottom and going through every operation, from the most elementary to the most difficult and refined. . . . The mere reading of books and attendance on lectures will never, in my judgment, make any one even a moderately competent gardener." This looks like a common-sense way of putting it. At any rate, one would not expect practical gardeners to do other than endorse every word here quoted. On the other side it is held by some that the teaching is not for professional men, but for farm-laborers, allotment-holders and women. Others ask if the English gardener of the present time is as good as his father, and go so far as to say he is no better, though he ought to be. They say he may be a better gardener, but he reveals a lamentable want of schooling when compared with the foreigner. I hear, too, that gentlemen complain of the want of polish in their gardeners, which makes them less pleasant companions in the garden than is desirable. Altogether, these critics seem to think that professional horticulture in England is in a very bad way. I had thought hitherto that England was the best horticultural school in the world, and that men trained here were in con-

stant demand wherever good gardening was wanted, whether in America, Australia, New Zealand, India, and even some Continental countries. I had entertained a suspicion that the several million pounds' worth of fruit annually imported into England was very largely sent here by enterprising Britishers who had settled in other countries where good fruit could be grown at less cost than in England. It appears from what is now written and preached that all this is ridiculously wrong, and that we need to supersede the old-time gardeners with a new and superior stock developed by means of lectures and magic-lanterns.

London.

W. Watson.

[Of course, the way to learn an art is to practice it rather than to read about it. But if in addition to this practice the

In addition to the numerous species and natural varieties, a number of hybrids have been raised in European gardens, such as the attractive and extensively cultivated *E. hyemalis*. These hybrids are generally easier grown, more robust in habit than the species, and equally floriferous.

In Europe, and especially in England, enormous quantities are grown every year for the market for house and parlor decoration. The general size of the plants brought to the London market varies from eight to eighteen inches in height. All are perfect in shape, healthy, and covered with flowers. The kinds generally grown for this purpose and kept on the market from autumn until spring are *E. caffra*, *E. hyemalis*, *E. gracilis*, *E. colorans*, *E. hybrida*, *E. ventricosa*, *E. Cavendishiana* and *E. persoluta alba*, but many other varieties are grown for commercial purposes.

While the moist, equable climate of England is favorable for

pupil is judiciously instructed in some of the principles of the sciences related to the art, he ought to be a more intelligent practitioner and a broader man.—Ed.]

Cultural Department.

Ericas.

THE ornamental *Ericas* of the Cape of Good Hope number between four hundred and five hundred species. They are neat plants, with closely set foliage and an abundance generally of small cup or urn-shaped flowers, but sometimes with larger, tubular ventricose corollas with well-developed segments. Some are very fragrant, as the favorite white-flowering *E. caffra*.

the growth of *Ericas*, there is no reason why they should not be grown to equal perfection in this country. The bright summers will tend to ripen the shoots well and produce flowers in profusion. They do not like artificial heat, but will do well in a winter temperature of from thirty-five to fifty degrees. This can be had during a considerable part of the winter without resorting to fire-heat. If kept in a cool and somewhat shady position during the hottest part of the summer, they are not likely to be injured by the extremities of the climate. Systematic cultivation is, however, essential; and it would hardly pay to go through all the details with a small number of plants in order to grow them for the market to perfection. Cultivation for commercial purposes is likely to be profitable only when carried on on a large scale.

Without giving a list of the most desirable kinds, it may be said that, in addition to those already named, there are many

others which are interesting from every point of view. They may be had in almost any color from pure white to yellow, or through various shades of pink and red to purple. They differ widely in habit of growth, in shape and disposition of flowers and leaves. Some of them bloom in October, and a succession of flowers can be had until May.

The propagation of *Ericas* from seed requires much care and patience. The seeds are very minute, and the young plants tender and liable to damp off in a dull season. Still, as new and valuable varieties may be raised by this means, it is sometimes resorted to. The seed should be sown as soon as ripe in well-drained pots of finely sifted peat and silver sand. Pack the soil well in the pots by shaking them, and if the soil is very dry it should be thoroughly soaked before sowing. Sow the seeds evenly, and a gentle sprinkling will cover them sufficiently. The seed-pans must be kept in an even temperature of about sixty degrees in a light greenhouse. The air should be pure and dry, while the pots should be kept moist, without too much sprinkling, which will cause the seeds to decay, especially if they are old. Each pot should be covered by a pane of glass, and this must always be kept free from moisture, especially at the time of germination. Moist or overheated air at this period is almost certain to cause serious loss. When the plants are large enough to be handled they should be pricked off in other pots or deep pans of well-packed soil. After this they must be kept close until a strong healthy growth has begun. Water containing alkaline or mineral substances in solution should be strictly avoided. Rain-water is at all times the best for *Ericas*.

When the flowering season is over and growth commences a number of young shoots will be formed at the base of almost all larger plants. These shoots invariably give the best cuttings. As soon as they are half-ripe these shoots, with their lower leaves removed, should be cut, inserted obliquely in shallow pans filled with the same kind of soil as for seeds, except it may contain more sand. It is of importance not to insert the cuttings too deeply; in fact, the base should be covered only sufficiently to keep them firmly in place. All pans should be covered with bell-glasses, which must be kept dry by wiping away, as often as possible, all water condensed on the inside of the glass. If a propagating-house entirely devoted to *Ericas*, *Azaleas* and the like is used, no bell-glasses are required. The stage of such a house should come close to the glass, and a couple of hot-water pipes will be wanted to supply a gentle bottom-heat. When in use for this purpose all ventilating ought to be given below the stage when this is necessary. Facilities for shading on very bright days should be provided. The pans containing the cuttings should be plunged to the rim in coarse sand. Only one variety should be inserted in each pan, so that the growth of all may begin at once. When the cuttings are well-rooted abundant ventilation is needed.

In the following spring the young plants are to be potted singly in two-inch pots, and if kept in close frames for some time they will soon root well. As the plants go on growing attention must be paid to repotting before they become pot-bound, and the young shoots should be trimmed to make the growth dense and uniform.

Young plants should be repotted every spring and removed to the open air early in summer. Beds should be prepared in the open grounds for this purpose by covering them a couple of inches deep with cinders or ashes and leveling the surface. The beds are made four feet wide, and the plants placed at a sufficient distance to allow light and air on all sides. Young plants must be trimmed several times during the season. They can be cut in such form as the natural tendency of each species suggests. This cropping should not extend below the soft wood. Plants for flowering must not be trimmed in this manner, as they must have sufficient time to ripen their shoots.

Ericas must never be allowed to dry up, but overwatering is very injurious. When potting, the roots must not be injured or disturbed except at the bottom, when the young roots should be gently disentangled and the soil should be packed in very firmly. Common peat, with very little sand, is best for the more robust, soft-wooded kinds, which can also be potted less firmly than the smaller hard-wooded species, which in their native land grow in crevices of rocks, on hard stony ground, chiefly in soil produced by their own decaying leaves. For old and large specimens it is advisable to put some bone or horn-shavings in the bottom of the pot or tub, or use well-decayed cow-manure.

During dull moist seasons *Ericas* are apt to suffer from mildew. The only way to counteract this evil is to sprinkle them with sulphur. If planted too deep the water is liable to cause

the bark of the lower part of the stem to loosen and decay. It is better to plant a little too shallow than too deep.

The Value of Wind-breaks.

WHEREVER winds have a destructive sweep there is a lack of those provisions that nature would supply if let alone. Run an old-fashioned fence across a lot, and in ten years it would be the centre of a row of young trees, forming a solid wind-break. On knolls hereabout, if barred from cattle, Hemlocks and Pines start. Fifty years ago I dragged rails to enclose a bit of land, which, to my boyish eye, was a delightful spot, where some tiny evergreens were trying to get a start on ridges and slopes and knolls. I was not interfered with, and so the cows were shut out. The result is now a thing of beauty. But that is not all; the winds that used to leap off the hill-top down on our orchards and barns are now decidedly broken. The only conifer native to our hills is the Hemlock, and its beauty is hardly equaled. But the *Arbor-vitæ* readily takes to our soil, and I have used that for my hedges. Under the lee of these the sharp winds never are felt, and the effect is largely to restore climatic conditions that existed before the forests were so extensively cut away. Quinces, for example, bear once more as they did fifty years ago.

On one side of a street here fruit abounds that cannot be grown across the way. I have no trouble with *Diana*, *Isabella* and *Iowa Grapes*, while even *Concords* do not get a fully ripe flavor a few hundred rods away. This is, to be sure, owing partly to the contour of the land, but it is also due largely to the additional protection given. The advantages are not only general, but special and local; we cannot only affect climate on a large scale by forests and by our plantations of screens and wind-breaks, but we can make our own lawn or orchard climate.

Where land is abundant a belt of evergreens may be set. I have in mind one large orchard in this town, about one-third of which is sheltered in this way, and is in perfect health; two-thirds are exposed to the sweep of north-west winds, and the trees are of no use except for fuel. The line of demarkation is plain to every one who drives by, and the contrast is almost startling. The effect on annual crops may not be so apparent, but it is logically sure. I am confident that one of the first duties of a purchaser of land is to study its exposure and plant screens against the most trying winds. While we are waiting for the Government to solve the forestry problem, we can in a small way control our own local climates to advantage.

Alternanthera Leaf-blight.

DISEASED specimens of *Alternantheras* have been recently received from four widely separated greenhouses in the eastern states, and a visit to several propagating-beds in New Brunswick shows that the trouble in question is prevalent here. In its worst form the leaves blight, coil up and fall away, leaving the short stems of the plants bare. When the disease is in a mild form only, here and there a leaf is seen with a brown spot upon one side or at the tip. These spots contain countless threads of a parasitic fungus, pushing into the healthy portions of the leaf and spreading the spot. Upon the older portions of the brown patch a considerable number of nearly spherical buds may be seen half-sunken within the substance of the leaf. At the upper free side in the centre is a small opening, through which, when mature, the small colorless spores exude in large numbers, and by means of which the blight fungus is able to spread through the propagating-bed. This disease is caused by a species of *Phyllosticta*, which, while probably not the same, is closely related to *Phyllosticta Amaranthi*, upon a species of Pigweed (*Amaranthus retroflexus*), a near neighbor of the *Alternantheras*, and a member of the same family. One reason why this blight is not particularly conspicuous is due to the variegated foliage of the host. Upon plants with uniformly green foliage a blight equally abundant would be quickly observed. It is, however, none the less destructive because not easily seen, and should it continue to prevail it is quite certain that some preventive measures will be needed. As this blight is similar in nature to the black rot of the Grape, it is doubtless true that the Bordeaux mixture would prove effective. Better than this, because not coating the plants with lime, would be the carbonate of copper compound, made as follows: Dissolve three ounces of carbonate of copper in one quart of ammonia, dilute with water to twenty-two gallons, and spray the affected plants at least once a week.

There are so many fungous enemies in the greenhouse that the spraying-pump will come to be a regular adjunct to the propagating-bed and to the growing of plants under glass.

Galvanized Iron for Propagating-beds.

IN building a greenhouse five years ago I made a propagating-bench of the usual width and fifty feet in length. As a test, half of the bed was laid with a slate bottom and the other half with galvanized sheet-iron. The experience of these years does not show any essential difference in the rooting of cuttings in the bed. The bottom-heat does not seem to vary with the slate or the iron, when the average depth of three to four inches of sand is used as a covering. It is probable that less depth of sand and careful tests would show a higher temperature on the iron than on the slate; but in our ordinary use of the greenhouse there has been no appreciable difference.

It has been a surprise to me that the galvanized iron shows no sign of wear. The bed now looks as though it would last as long as the two by three-inch scantling upon which the sheets and the slate were laid. Having had the same satisfactory results in the use of sheet-iron in other places, I decided this season to use the sheets as a bottom for propagating-beds which we were building. As the houses were constructed mainly for one purpose, the result has been more than satisfactory. The beds can be maintained at any desired degree of temperature and moisture with the greatest ease. In some houses and under some management there might be danger of an excess of moisture in the sand for some cuttings; but in such cases it would be easy to provide drainage by punching holes in the sheets, as might be found necessary. Ordinarily, this would not occur.

In regard to cost, I find that the sheet-iron comes next to boards. For a heavy quality the cost is \$4.50 per 100 square feet. Considering the ease in laying, this must be regarded as a moderate expense; and considering the very satisfactory results, it seems to me that it is worthy of more general use.

Wm. C. Strong.

Barberis Thunbergii.—Those who desire to increase their stock of this handsome shrub will find this a favorable time to sow seeds. Seeds from berries gathered from the bushes now will germinate better than those gathered earlier in the season, as the weathering effects of frost seem to help germination. The seeds should be rubbed clear of the pulpy matter which encloses them, as berries planted whole will sometimes lie in a dormant state for two years, or, at least, until the resinous matter surrounding them has decayed. Even with this precaution, it takes nearly a whole season for the crop to come up. Like almost all Barberries, this species is very easily reared, and seedlings may be planted directly from the seed-bed as soon as they are large enough to handle. This, probably, is the best of all the Barberries which are hardy in this latitude. *B. Darwinii* and *B. stenophylla*, two equally handsome species which are evergreen, at least in southern Europe, are doubtfully hardy here. With full exposure, *B. Thunbergii* makes a neat and perfectly regular bush. There is at the Bussy Institute a remarkable specimen, being one of the first raised in this country, which every autumn is covered with thousands of scarlet berries, and is so conspicuous an object that it attracts attention from a considerable distance. The berries hang on the bushes until spring, as no birds or animals seem to care for them.

The Forests of Washington.

To the Editor of GARDEN AND FOREST:

Sir,—The forests of western Washington are inconceivable to those to whom the word forest suggests a vision of sun-lit green. Green they are, but it is the sombre darkness of the conifer. To the woods of the Blue Ridge they are as the movement of Milton's lines to the lilt of Dobson's song.

Imagine yourself seated in an old stage, with a pair of Cayuse ponies hitched to it, and driving for the first time, on a December afternoon, through a belt of Washington timberland. The timber skirting the stage-road will, of course, be very inferior, since the road has chosen the direction of least resistance; but in your innocence you will not guess this, and will promptly conclude there never was another spot just like this peculiar one where you find yourself. It is mid-December, but the air is like one of the misty days of late October; and the grass on the road-side has a vividness of green, a cer-

tain mossy depth of color, as though the earth were covered with layer upon layer of tiny-leaved grass that is like nothing but the spring grass of Great Britain. There are no flowers by the side of the road, but Ferns in the wildest luxuriance. They range in size from the minutest seaweed-like tracery of green to the Elk Fern, as tall as a man, and with the decorative vigor of a tropical Palm. Above all this, so far above as to seem of another world, reach the forest-trees. They are all evergreens. Round-bodied, straight and flawless, they stretch upward one, two, and even three hundred feet. They are so tall that one scarcely observes the slightest tapering in the majestic columns at the point where at last they throw out the first limb, laden with heavy foliage of down-drooping darkness. There are not twenty or a hundred of these trees in range as you creep along, but tens of hundreds; they grow as closely as Hop-vines in a Hop-yard. The wonder that ever increases is how the soil supports such a growth.

In many places the trees have fallen, and lie tangled together, forming a barrier twenty or thirty feet high. If they should all fall the pile they would make would be about as high as the trees now stand. The density of the forest makes it almost impenetrable; for, beneath the up-reaching Pines, the ground is covered with the tough tangle of Sallal (*Gaultheria Shallon*), hung with pink waxy bells, which enmesh the feet at every step; and the riot of the Ferns, that snap back into the face, further impede the way. Four miles is as far as a strong man can walk in a long day's struggle with the baffling, entrapping blockade of living green.

The gigantic conifers and the immense Ferns are the living representation of those pictures of the carboniferous age that decorate the pages of geologies. We seem to have prowled into Nature's laboratory, and caught her at coal-making some eons too soon. Many beds of coal have been discovered; but it is lignite coal, still soft and half-formed. The stone, too, is crumbly and unfinished. The whole energy of the black mellow soil goes into the monster evergreens, and there seems no place for flowery frivolities beneath their sombre magnificence. This is in the interior of the woods. Down near the salt-water of the Pacific the character of the growth changes. There the Tide-land Spruce (*Picea Sitchensis*) prevails, a scrub growth, averaging about one hundred feet in total height, and of a gnarled and irregular figure. Upon every notch or crotch of the limbs is a clump of moss, so vividly green that even the grass pales in comparison; and, from this bed of mold, spring hundreds of Ferns, but always of one sort, with a delicate but simply pinnate frond.

The curious excrescences of moss give the Tide-land Spruce an unnatural look that is slightly revolting; it takes the character from the trees' anatomy; but, in themselves, these bosses of green, pierced by the Fern-ironds, are lovely. The south sides of many of the trees are covered with this deep moss, and from it the Ferns cascade downward to the ground.

Among the Tide-land Spruce are patches of small Alders, gray for the season, and grayer with fine filmy Spanish moss, hanging in shreds, and giving a ghostly indefiniteness to their outlines. Under-foot the same vivid moss and Ferns, only the Alders, stretching their twigs like a seine in which filaments of seaweed have been caught, speak to us of winter in this climate of moist mildness, in this "land where all things always seem the same."

Bergen Point, N. J.

Louise Herrick Wall.

The Hardiness of certain Evergreens.

To the Editor of GARDEN AND FOREST:

Sir,—Your correspondent, Mrs. Dandridge, suggests reports on the hardiness of certain evergreens. In this neighborhood English Laurels do not survive, even when given slight protection. I have never seen one left outside for the winter that was alive in spring. *Aucuba Japonica* does well where it gets a little shelter; near a dwelling or under the shelter of deciduous shrubs it will survive without any covering. *Hydrangea hortensis* and *H. Otaksa* are never killed outright by the winters here, but trying seasons sometimes kill the ends of the branches, and then we get no flowers, for the flowers are produced on the wood of the previous season. So, to be sure of bloom, it is better to pack leaves among the tops. I had no idea that *Chimonanthus fragrans* was considered tender. We never protect it hereabouts, and it is never injured. *Deodar Cedars* do very well when protected for a few years while small. There are very fine specimens here, one in particular, which stands on a rocky eminence. There are several flourishing trees of the great evergreen *Magnolia* about us, and many more could be had if they were intelligently looked after for a few years after being planted. A

great step toward success is to get plants from seeds perfected near home. Seeds from Washington or Richmond trees would give a hardier race of seedlings than would those from farther south. I would advise Mrs. Dandridge to cover the top of her plant with forest-leaves instead of having it protrude from the barrel. In late winter it is the extreme tops that suffer. Over a small Magnolia I have placed this winter a box with a removable cover. When it is not freezing weather the top is taken off. There are no leaves packed about the plant, and I feel confident that the shelter the box affords will suffice for its protection. *Yucca angustifolia* is quite hardy, but *Y. gloriosa* is not. The latter lives, but loses its tops nearly every winter, so that it makes no trunk. The pretty shrub, *Leycesteria formosa*, so well known in English gardens, survives our winters. And we are trying again this winter, although we lost our plants on a previous trial, *Choisia ternata*, *Ilex cornuta*, *Nandina domestica* and *Elæagnus pungens variegata*.

Germantown, Pa.

Joseph Meehan.

Meetings of Societies.

The Western New York Horticultural Society.—I.

THE thirty-seventh annual meeting of this prosperous society last week at Rochester brought together 250 of its 300 members. The address of the President, Mr. W. C. Barry, was a comprehensive review of the horticulture of the past year. The abundant crops of fruit and the comparatively small returns was the strongest proof, he thought, that the grower should exercise the greatest care in packing and shipping his products. The loss from lack of careful sorting was never so apparent as in years of plenty. The importance of recent discoveries in the methods of combating injurious insects and the diseases of fruit-bearing plants was spoken of, and credit was given to the aid which experts in economic botany and entomology were giving to practical fruit-growers. The possibilities of the improvement in fruits and in ornamental plants were dwelt upon, and the society was urged to encourage every effort to produce fruits surpassing the varieties now in use, in size, in color, in appearance, and of increasing the beauty and attractiveness of flowers and ornamental plants. The society was congratulated on the work it had accomplished, on the harmony which had prevailed through its history, on the regularity and growing interest of its meetings and the steady increase of its membership.

As in former years, discussions relating to orchard-fruits, especially to apples, pears and plums, were the prominent features of the meeting. Not only did the greater number of the set papers relate to these subjects, but the discussions which followed them, and which were participated in by a large number of the audience, showed that the members were deeply interested and thoroughly schooled in the practice of the new methods. Papers referring to plant-diseases and their treatment were followed by searching questions, to which the experts present replied, and many practical growers related their experience in the application of insecticides and fungicides. As a rule, these applications were reported as beneficial, and this was particularly true of the applications made to nursery stock. There seemed to be a general opinion that ammoniacal carbonate of copper was preferable for later applications in the case of fungous diseases of the Grape after the Bordeaux mixture had been used early in the season. The objection to the use of the Bordeaux mixture late in the season was that the traces of the fungicide remained upon the fruit, and although analysis showed that the amount of copper upon the grapes was less than the amount present in many of the foods which are continuously eaten by man, nevertheless the appearance of metallic coating on the grape was forbidding, and it should be avoided if possible.

There are no more valuable reports published than those of the meetings of this society, and, therefore, it is a matter of general interest to know that a larger supply will be printed and distributed hereafter. The expense of the printing of these reports will hereafter be borne by the state, and they will be bound up with the reports of the

State Agricultural Society, and in this way have a wider circulation.

Mr. Wm. C. Barry was again elected President; Mr. S. D. Willard, First Vice-President, and John Hall, of Rochester, Secretary and Treasurer.

One of the most interesting of the papers read was by Professor I. P. Roberts, of Cornell University, and we reproduce it below almost entire. Our report of the meeting will be continued next week.

MAINTAINING THE FERTILITY OF THE SOIL IN ORCHARDS.

If the land produces well, we usually call it fertile; if it produces nothing, we say it is barren; and yet the land which produces little or nothing often contains far more of the elements of plant-growth than does the productive soil. The products of cultivated land are not, as a rule, the measure of the amount of plant-food which it contains, nor the amount which may be liberated by scientific culture. In our farm vernacular fertility means production, whereas it should mean the amount of plant-food which can be profitably set free by the best methods. To the orchardist the amount of plant-food which the trees can get out of the land is practically the true measure of the fertility of that land.

Now, the roots of an orchard, after it is fairly well grown, occupy very fully the entire ground except a small portion of the surface. From this time on, the feeding roots are practically confined to the exact ground from which they have been feeding for the last fifteen or twenty years. The roots of fruit-trees set the ordinary distance apart have extended themselves nearly as far into the subsoil at fifteen years of age as they will ever go, because there is little more food that can be reached in that direction. The surface roots have by this time extended themselves as far as they will grow, because they have met and interlocked with those of the adjoining rows.

How to get the orchard grown up to the time when it is in full bearing is now to be considered. First, the land should be reasonably dry. If it is very wet, it should be made dry by draining; if only slightly wet, the field may be thrown into ridges as wide as the rows of trees are to be apart, and if the plan is not to drain the land after the trees have begun to bring an income, then the rows and ridges should be wider—that is, a little land may be sacrificed in order to save the expense of draining, and where the land is not too dear, this is often the cheapest way to solve an embarrassing problem. Having decided the method of drainage, a full year should be given to preparing the land. It should be plowed deep and often, and if thrown in ridges or lands the subsoil-plow should be used freely in the bottom of the dead furrows. If the land is at all sandy and poor the plowings should be not less than four, and none of them should be later than the middle of September. With this start, for the next five to fifteen years, according to the variety of trees set, enough plant-food can easily be set free by shallow plowing, cultivating and the use of surface crops. Many a young orchard is ruined by overfeeding with manures, as are also many by starvation, while the soil contains an abundance of food for all necessary growth. The tree is too often treated like the unwise dairyman treats his stock, which are fed to repletion when young, and semi-starved at maturity, when the demand for food is great, especially if a large surplus product is to be secured. Healthy, continuous, hardy growth, and not too much stimulating nitrogen, is what is wanted in both cases.

In rare instances the land may be deficient in fertility. In that case, a little mineral fertilizer will be all that is needed. When the orchard begins to fruit heavily there will be an extra demand on the soil for food, and that must be met quickly and in a liberal way if large, superior fruit is secured. As the roots have been drawing upon this soil for several years, and as they can find no soil from which they have not already extracted the larger part of the readily soluble food, the tree suffers; the quality and quantity of the fruit diminish, and the tree becomes an easy prey to its enemies if something is not done. Something usually is done at about this period of the orchard's existence. Not infrequently it is seeded down to Timothy, and very often this grass is cut for hay, and thus more fertility is taken from the land. Of course, the Apple-orchard cannot well be kept under the plow all the time after it has come into full bearing, because of the inconvenience of gathering the fruit on a plowed surface in the wet fall months. There is usually a better way than this. Clover should be raised so far as possible in the orchard, and it is not necessary to plow it up often, as Clover catches on sparsely-seeded land, nearly as well without as with plowing. This treatment usually

provides sufficient nitrogen in conjunction with a little farm-manure.

It should be kept in mind that we are dealing with trees that have occupied the ground for several years; that have creamed the soil; that have already trespassed upon and robbed their surrounding neighbors, and that in turn have been robbed; and there is no escape from slow starvation if the trees are reasonably thick and nothing is done.

And first it should be remembered that, for the good of the trees and of the land, and for the total value of the product, the amount of fruit raised on a tree should not be large, and the quality should be of the best. Bearing this in mind, some questions arise. Is it not possible to prune the orchard by the same rules which are observed in trimming Grape-vines? Our grandfathers let their vines grow as they would, and they never produced any really fine bunches of grapes. As soon as we learned to control and direct the growth of the vine the value of the fruit increased a hundred-fold, while the least possible amount of fertility was removed from the land. Is it not quite possible that fertility might be conserved, and the quality of King apples, say, be improved by reducing the length of the limbs upon which they grow? Is it true that the nearer the total product of fruit is to the food-supply of the tree the better the results? or, to state it in another form, Are the apples improved when the material of which they are formed is transported eighty feet through root and branch before they receive it? Is the soil of the orchard unnecessarily drawn upon by growing too much timber?

We assume that the fertility of the orchard has been maintained up to the time of its bearing. What I have said also implies that the trees have not been unduly forced by manure, but have made a steady, healthy growth, and have come into bearing early. Just as a heifer is simply kept growing and great care is taken not to overfeed or change the direction of her inbred tendencies while she is young, and as she is more liberally fed as soon as she begins to produce something, and as she is fed moderately, liberally or very liberally, according as she responds to the food given, exactly so should the orchard be treated. The amount and kind of food furnished to it should be studied as carefully as is the ration of the dairy-cow. What kind of food does the orchard want? Like other plants, it is likely to have enough of all kinds except potash, phosphoric acid and nitrogen. How shall it be secured? Would it be best to get the annual dressing of fertility wanted by purchasing commercial fertilizers, or by the purchase of cattle-food, to secure the desired elements in the form of farm-manures by the help of animals?

If the orchard contains ten acres, it will carry one hundred sheep from May to October, provided one-fourth of their food be furnished to them in the form of bran and cotton-seed or oil-meal. One hundred sheep, weighing eighty pounds each, will require for one-fourth of their daily sustenance one-half pound of meal per head. In the spring they will want something less than this, in the fall something more. If these animals take ten per cent. of the manurial value from their food for their natural growth, there will still be left scattered on the land in solid and liquid droppings 228 pounds of nitrogen, 146 pounds of potash and 90 pounds of phosphoric acid; or 22.8, 14.6 and 9 pounds respectively per acre.

One hundred and fifty bushels of apples—that is enough to the acre if they are good enough, and too many if they are poor—contain about eight pounds of nitrogen and twenty-four pounds of ash, thirteen pounds of which is potash, and one pound of phosphoric acid, worth together \$1.86.

How much the trees will require for increased growth, how many of the leaves will be blown away, how much nitrogen will escape by leaching and how much will be restored to the soil by the clover-roots, and how much of the fertility produced by feeding the bran and meal the trees will be able to readily secure, neither the theorist nor the practical man can tell. No charge should be made the sheep for the grass, as the work they will perform in transforming the poor apples and the worms into valuable fertilizers will be a fair equivalent for it.

Summing up the case, we have the orchard raised through skill and the unaided fertility of the soil. The draft made on the land by the production of apples and the necessary growth of wood, and the losses of fertility which may occur, are to be fully met by restoring to each acre yearly, through feeding animals upon it, some twenty-three pounds of nitrogen for the eight pounds removed by the apples, fourteen and a half pounds of potash for the thirteen removed, and nine pounds of phosphoric acid to replace the one carried off. It will be seen readily that if there is any deficiency it is likely to be in the potash, as scarcely more is returned to the soil than is re-

moved by the fruit; so a dressing of potash is likely to not only improve the quality but the color and aroma of the fruit as well.

The hundred sheep would consume in five months at pasture 3,750 pounds of oil-meal, worth \$28.00 per ton, and a like amount of bran at \$17.00 a ton, and the two would cost together \$82.50. The value of the plant-food left on the soil, computed at commercial prices, would be \$43.07; but whether it is really worth that or not no one can tell. Can a hundred lean sheep, purchased in the spring, be made to gain \$100.00 in value in five months of grazing and grain-feeding with a half a pound of meal per day per sheep, or with the feeding of three-fourths of a pound, if thought advisable? I cannot answer these questions accurately myself, and I leave them for your consideration. Yet I believe that the orchardist is growing too much wood, too many apple-seeds, too many apples, too poor apples, too many badly colored and badly flavored apples, and that this may be remedied by heading back the trees in lieu of thinning them, and by furnishing to the bearing orchard yearly a reasonable amount of available plant-food, largely through the aid of plants and animals. I am well aware that the methods here suggested will have to be varied to suit local conditions; still I claim that the principles involved are correct, and that if they are intelligently practiced in connection with the best-known methods of defending the fruit from its enemies, a great advance will be made.

In the Peach and Plum orchards the practices which I have suggested are not likely to be the best, as it will be found advisable, in most cases, to keep these constantly under cultivation. But here, as in the former case, fertility may be preserved by feeding animals during the winter, and by preserving and removing the manures produced to the orchards. I have the utmost faith that this method of getting plant-food, through plants and animals, will be found to be the most economical in most cases.

I contend (1), that the soil should be cultivated and plant-food set free to the utmost limit; (2), that leguminous and tap-rooted plants should be used as plant-food gatherers; (3), that animals should be kept as much for the value of the manure they produce, as for the profit realized from their other products; (4), that the least possible amount of stalk and vine and limb be grown consistent with economy and the health of the plant; and (5), after having practiced all the economy possible, if there is still a lack of fertility, in order to secure the highest quality of product and the greatest net income, that commercial fertilizers of a high grade should be applied with a liberal hand. If it is found at any time that commercial fertilizers give better net results than farm-manures, then there should be no hesitancy in changing from one to the other. I believe that farm-manures which have lain in the open yards or have been heated, and which have to be drawn long distances, are far more expensive than are high-grade fertilizers. Well-preserved manure is worth, on an average, scarcely more than \$3.00 per ton, and our experiments prove that such manure, exposed in piles from April to October, often loses one-half of its value; therefore I am led to believe that many tons of manure which are transported from the city contain less than a dollar's worth of soluble plant-food. This manure may act beneficially as a mulch, but, so far as the plant-food it contains is concerned, it is too often an expensive way of preserving the fertility of the land.

Notes.

At the late meeting of the American Forestry Association the committee on Arbor Day reported that the day was now officially recognized and observed in thirty-seven states and territories.

We learn that by the fire which last week consumed the greenhouses of H. Meyers, of Passaic, New Jersey, more than 3,000 plants of *Clematis paniculata* were lost. This shows the growing popularity of this plant, which is of comparatively recent introduction. Fortunately, time enough still remains to get up a stock for the spring trade.

Messrs. Burpee & Co. publish a circular in which it is stated that the Bush Lima Beans which they distribute originated with Mr. Asher Palmer, of Chester County, Pennsylvania. The story goes that this particular plant, found in a field of ordinary Lima Beans, had been cut off about half an inch above the ground by a cut-worm, but that it had bent over and rerooted, and the result was the Bush Bean.

Professor L. R. Taft, horticulturist of the Michigan Agricultural College, publishes the following list of varieties of Beans

which have proved satisfactory at the experiment station there: Wax Beans—Cylinder Black Wax, Speckled Wax, Saddleback and Mammoth Wax; Green-podded varieties—Osborn Forcing, Dakota Soup, Hatt No. 3 and Shah; for field-culture—Burlingame, Snowflake and Hatt No. 2½.

According to Mr. Conder, who has written so much about the flowers of Japan, the Japanese cite 269 color varieties of the Chrysanthemum, of which 63 are yellow, 87 white, 32 purple, 30 red, 31 pale pink, 12 russet and 14 of mixed colors. A fancy prevails in the country that in this flower the same tint is never exactly reproduced, and that in this it resembles the endless variety of the human countenance.

In the recent report of the Superintendent of Public Instruction of the State of New York it is said that the interest in the planting of trees on Arbor Day and at other times has been greatly stimulated throughout the state during the past two years, by prizes offered for the best-kept district school-grounds by Mr. Wm. A. Wadsworth, of Geneseo. Last year the first prize of a hundred dollars was awarded to District School No. 6, of New Windsor, Orange County, and the second prize of fifty dollars to District School No. 1, of Manheim, Herkimer County.

Professor Bailey, of Brown University, writes in *The Bruonian* that the custom of planting class trees was begun there some thirty years ago, and that a great deal of eloquence and sentiment was expended over the young plants. Every tree is gone, however, the ground having been occupied for other purposes in most cases, although we infer that some of the trees perished from lack of care. He points the moral that if trees are to be planted in future they ought to be placed where there is a reasonable certainty of their remaining, and he might have well added they should never be planted unless they are planted well and there is a reasonable certainty that they will be well cared for afterward.

In a letter to the American Forestry Association, ex-Senator Edmunds writes: "The subject of forestry is of immense importance to the future welfare of all our countrymen, as well in Vermont as in the arid regions of our one country. I have seen in Europe much of the remediless evils of stripping the hills and mountain-sides of their forests great or small, and I have seen in our temperate and well-watered climate of Vermont how great has been the loss from reckless timber-cutting. The devastations of a dozen years can hardly be repaired in half a century, and so every energy of reason and persuasion ought to be brought to bear upon the public intelligence to avert the evils that so seriously threaten large parts of the republic from the destruction of the forests."

Professor Georgeson, of the Kansas Agricultural College, raised last year a crop of the Japanese Soy Bean (*Glycine hispida*), and offers to distribute them to such farmers of his state as are willing to try them. They are unknown, we believe, to the agriculture of this country, although sixty varieties of them, varying much in size, color, earliness, etc., are in use in Japan, and they have yielded in Kansas from twelve bushels to nineteen bushels an acre on low ground which was too wet for proper cultivation. Professor Georgeson thinks these beans, on account of their nutritious qualities, will prove valuable for farm crops and useful for stock feed, while, at the same time, they are excellent for table use. Professor Georgeson also offers for distribution two varieties of a small red bean which belongs to the species *Phaseolus radiatus*, also unknown in this country. They are more especially for table use, and are reputed to be the finest-flavored beans in existence.

A correspondent of *Meehan's Monthly*, in writing of *Dentaria diphylla*, in many places called Crinkle Root, on account of the peculiar shape of its roots, and Pepper Root in other places, on account of the pungent taste of its roots, states that the roots dried and pulverized have long been used as a condiment by the Canadian Indians just as it was used, according to Michaux, by the Indians of the Carolina mountains. To many persons these roots are quite palatable, and Mr. Meehan endorses the opinion of his correspondent that it is surprising that this root has never been introduced into vegetable-gardens. Many garden-plants, like the Radish, Turnip, Horseradish, etc., belong to the same family, and, in their improved state, have become necessities of life, and yet, when quite wild, they seemed no more promising as food-plants than the Crinkle Root. By judicious cultivation and selection it is probable that this root might be improved so as to be a valuable addition to our food-supplies.

A circular from the Horticultural Department of the Columbian Exposition states that a Rose-garden has been designed

on the grounds to contain not less than 50,000 plants, besides special areas for other groups. As substantial premiums are to be offered for Roses in addition to the awards that are to be offered by the National Committee, Rose-growers are invited to prepare plants for this garden. Hardy Roses on their own roots must be in three and a half-inch or larger pots of the current year's growth, or they may be dormant plants one or two years old. Of course, Tea Roses, Noisettes and other tender kinds will require different treatment, and it is suggested that strong plants in five-inch pots be carried over in cold frames for planting early in the spring of 1893. It is also proposed to have large displays of herbaceous plants during their best season of flowering from the 1st of November, 1892, to the 1st of April, 1893, including Chrysanthemums, Cyclamens, winter-flowering Primroses, Cinerarias, Calceolarias, Amaryllis, Dutch bulbs and the like. Instructions have been sent to the various firms who propose to contribute flower-seeds, that plants are to be grown from them in the most approved manner without expense to the contributor, and it is expected that awards will be made for the plants produced in the order of their merit.

"The treasures of the common are endless," writes Mrs. Martin in her *Home Life on an Ostrich Farm*, of the neighborhood of Walmer, in Cape Colony, "and first and loveliest among them all is the little Wax-creper (*Microloma lineare*), than which, tiny as it is, I do not think a more perfect flower can be imagined. It is as modest as a little Violet, and you have to seek it out in its hiding-places under the thick foliage of the bushes, round the stems of which it twines so tightly that it is a work of some time to disentangle it. You also get many scratches during the process, for it loves to choose as its protectors the most prickly plants; but when at last you hold the delicate wreath in your hands, and look into its minute beauties—the graceful curves of the slender stalk and tendrils, no two of which ever grow alike; the long narrow dark green leaves, and the clusters of brilliant carmine-tinted flowers, each like a tiny exquisitely shaped vase cut out in glistening wax—you are amply rewarded. It is, indeed, one of the masterpieces of nature. This little flower does not bear transplanting well. We often tried to domesticate it in our garden, but the plants invariably died. It was quite the rarest of all our flowers. We have never seen it anywhere but about Walmer, and there it grows only in small patches, five or six plants close together, and then perhaps no more of them to be seen during the whole of a long walk."

Parks for Growing Cities.

THE article by Mr. Baxter in another column referring to the proposed metropolitan system of parks for Boston has more than a local interest. Our rapidly growing cities will all be compelled, sooner or later, to face the problem of providing ground for public use, and the sooner the problem receives careful study the more perfectly and economically can the necessities of cities in this matter be met. There is no longer any need of argument to prove that ample and convenient open spaces for public resort and recreation are essential not only to the pleasure and comfort, but to the physical health and the mental and moral growth of the people. This is universally admitted. Twenty-five years ago the case was different. Men of high professional repute in this city, even as late as seven or eight years after the act to create Central Park had been passed, argued that additional pleasure-grounds would only offer more space for riot and disturbance; that no police force could preserve decency and order in such broad areas, where the lowest denizens of the city would congregate; that no gentleman would ever visit the park or allow his wife and daughters to go there.

No man in his right mind can now be found who harbors opinions of this sort. The park questions with which public-spirited men now concern themselves are, how to secure enough land, how best to adapt it to public use, and how to maintain and administer it most effectively for that end. These questions are growing more urgent because of the rapid increase of our urban population as compared with that of the whole country. In some states there are actually fewer people on the farms than there were ten years ago, and the cities now contain more than half of our entire population. This tendency is likely to be stronger for years to come, and the abandonment of the country makes it more necessary to supply the town with some of the country's advantages. In most cases the expansion of our cities outstrips prophecy, and [outlying districts are swal-

lowed up before any preparation is made for their future. Before any one realizes that a park may be needed the lands have become so valuable that the cost of any area spacious enough to give the city visitor a sense of enlarged freedom is appalling. The danger of delay in this matter is illustrated by the example of the cluster of large cities in New Jersey, just across the Hudson. Neither Newark, Jersey City, Elizabeth nor Paterson has any park worthy of the name. No doubt, it would pay even now to acquire land within reach of the centres of population in all of these cities, but had this been done twenty years ago a comparatively trifling expenditure would have been needed and the investment would have been paying liberal returns in the comfort, health and business prosperity of their population. If action is delayed twenty years longer there is little hope that any adequate provision for public pleasure-grounds will be made here until the cities are forced to demolish solid blocks of buildings to make room for grass and trees.

Nearly thirty years ago, in their report on the design of Prospect Park, in Brooklyn, Messrs. Olmsted, Vaux & Co. indicated on a map the beginning of a road from the southern entrance of the park, and made a suggestion that it should be a shaded pleasure-drive, and practically an extension of the park. Without laying down the course of this parkway, the designers stated that the ocean-beach would be its natural terminus, and it was added that a similar road might be carried through the rich country lying back of Brooklyn until it could be turned without striking through any densely occupied ground so as to reach the shore of the East River at Ravenswood. From this point, over high bridges thrown across the narrow straits into which the river is here divided, the parkway could be carried through a broad street directly into Central Park, beyond which was to stretch a system of sylvan roads leading to the northward. Such an arrangement would enable a man to drive in half a summer's day through the most interesting parts of Brooklyn and New York, their most characteristic suburbs and both of their great parks, with the long stretch of the Hudson, the Palisades in the middle distance, and the mountain-range in the background for a prospect at one end, and the foaming breakers of the Atlantic at the other, and "the whole might be taken in a circuit without crossing the same ground, and would form a grand municipal promenade hardly surpassed in the world for extent or continuity of interest." If this project had been promptly carried out that drive might have been taken now under trees of stately proportions. It is hardly possible now that any comprehensive scheme of this character, or like the one outlined for the greater Boston, can ever be adopted by the cities in New Jersey; but there has been a time when a system of parks and parkways might have easily been designed to link together the heights of Bergen, the Palisades and the Orange Mountains. This could have been done without occupying as large a park area, in proportion to the size and probable population of the combined cities in the year 1900, as London has to-day.

In many cities it would not be possible to secure a continuous line of parks and parkways, but there are many other advantages of a single plan on a comprehensive scale. All the varied wants that are supplied by open spaces can be met in this way alone. Every large city could have its ample tree-bordered avenue for festal meeting and procession, its zoölogical and botanic garden, its parade-ground, its children's playgrounds, with places for public meetings and ceremonies, music and fireworks, not to speak of sequestered gardens and broad, simple pastoral scenery, besides special features which the peculiar conditions of each city might offer. It is encouraging to know that the movement in Boston has begun before the opportunity for this magnificent provision for the future is lost. It is to be hoped that this example will be infectious, and that many other cities will arouse themselves to take decisive action in a similar direction.

IN the report of the Honorable Thomas H. Carter, Commissioner of the General Land Office, for last year, attention is again invited to the rapidity with which the most valuable timber on the public lands is being exhausted, and it is once more shown that the land laws are inadequate to protect either the public forests from unlawful appropriation or the interests of settlers in their legitimate use of public timber. The laws passed last year will help to remedy some of the evils, but there is need of a general law to ensure equal rights and uniform privileges without any discrimination as to localities or industries. Mr. Carter suggests that one provision of such a law might be to empower the legislatures of the several states and territories to enact laws not in conflict with the act of Congress to govern and control the cutting and disposition of timber on the public domain. He thinks this would bring the local government to the aid of the general Government in such a way as to be helpful. He also holds that there should be provisions in the general law to facilitate the acquisition of title by actual settlers on agricultural land to a limited area of timber-land, so that each individual could guard his own timber. Provisions of this nature should certainly be made cautiously, for there is nothing in our experience to show that either the states or individuals will exercise any care in preserving the woods. It is true that the general Government itself has never done anything to inspire confidence that there is any promise of safety for the forests while under national control, but the proposition that some carefully considered general law relating to public timber should be enacted is one that every intelligent man in the country will admit without argument. Such a law will not be fully enforced until there is a thoroughly educated public sentiment behind it, but the passage of the act will be one of the most potent influences in developing this sentiment.

The Boston Metropolitan Park Movement.

THE park system of the city of Boston, though far from complete, has educated the public to the value of parks, and a definite movement for a metropolitan park system has at last been set on foot. Chief among the factors that have aroused popular interest in the subject are the agitation in behalf of a public forest-reservation at the Middlesex Falls, the agitation relating to the Blue Hills, instituted through the medium of GARDEN AND FOREST, the example of Lynn in creating its noble public forest, the incorporation of the Trustees of Public Reservations, together with the quickened consciousness of the need of extensive provision for breathing-spaces and the preservation of features of landscape interest throughout the region over which an urban population is rapidly spreading.

Throughout the state of Massachusetts there is now a marked interest in park-improvements. A large number of the cities and several of the towns have taken action under the general park law. The majority of the cities and towns within an eleven-mile radius of the Boston City Hall have accepted the provisions of the act by popular vote, as required, and have either appointed park commissioners, or are about to do so.

But even if all these neighboring cities and towns should be favorably disposed, they could hardly act co-ordinately for a single park system without special legislation.

The Trustees of Public Reservations, in their efforts to gain possession of the beautiful tract in Belmont containing the Waverley Oaks, found that it was impracticable to obtain title by purchase, owing to the complicated ownership. The preservation of these noble trees could be assured only by exercising the right of eminent domain, and the metropolitan park system offered the best method to meet the case.

Therefore, by co-operation with the Boston Board of Park Commissioners, the Trustees of Public Reservations invited to a meeting the park commissioners and other leading officials of the several cities and towns in the metropolitan region, together with other persons interested. At this meeting Mr. Charles Eliot, Secretary of the Trustees of Public Reservations, made a clear statement, showing how little use had been made of the remarkable natural advantages of diversified scenery offered by harbor and sea-shore around Boston. The growth of the metropolitan population to nearly a million

people, and its rapid increase, made it essential to adopt practical measures for setting aside more ground for the public.

The conference was unanimous that action should be taken in a comprehensive way. A committee was appointed to petition the Legislature and to devise some plan for a permanent organization. Governor Russell is known to favor the object, and the Mayor of Boston endorsed it in his inaugural, and the appointment of a metropolitan park commission seems probable.

The most desirable points to secure will be the reservation of large tracts for public forests like the Blue Hills and the Middlesex Fells; the preservation of the sylvan and rural character of the river margins, and of the beautiful salt-marshes and the neighboring uplands of the tidal basins of the Charles, Mystic and Neponset rivers, so far as practicable; the taking of picturesque and historic spots and points of view like the Waverley Oaks, and the holding of the sea-shore for the public.

One gratifying fact made known at the conference was that Nahant Beach and the beach between Little Nahant and the main peninsula are the property of the town, and Mr. Frederick Law Olmsted has been requested to make a design for their improvement. These beaches form long and narrow necks of sand, connecting the two portions of Nahant with the mainland, like islands with a gigantic mooring. On one side beats the surf of the open ocean, on the other are the quiet waters of Lynn harbor. The highway runs along the crest of the beaches, and that is the reason why they are town property. The views from these beaches form one of the most beautiful, varied and extensive panoramas to be seen along the Atlantic coast. Lynn, with its background of rocky wooded hills, is particularly beautiful from these beaches. It was at his summer home at Nahant where Longfellow wrote "The Bells of Lynn."

The Park Commissioners of Lynn, besides the great Lynn Woods and the improvement of Meadow Park, which they are converting from a mud-hole into a playground in the heart of the city, also propose to give the Nahant beaches improvement a worthy terminus by laying out an ocean-side plaza at the point where the Nahant Drive meets the mainland.

A proposition was made to restore the forest-mantle, so far as practicable, to the islands in Boston harbor. The islands and mainland shores were originally well wooded. The trees were cut away, and the hope of any renewed growth was destroyed by pasturing the islands. Except on the southerly shore, the beauty of the harbor is marred by the bald, inhospitable look of the islands, with their hard, monotonous contours.

The Park Commissioners considered the question of reforesting these islands several years ago, and Mr. Olmsted made a valuable report on the matter. It was found that an expenditure of a few thousand dollars a year for a few years would restore the woods, so as to give agreeable diversity to the harbor landscape. A majority of the islands are owned by the city, and most of the owners of the others promised co-operation. The proposition was received with great favor, but it was killed at the City Hall. This result of municipal politics is to be lamented, for even one or two seasons' growth would have worked a transformation in the islands, and by this time their beauty would have been established.

The securing of the Middlesex Fells region as a public forest-domain will be made easier from the fact that various towns have enlarged their public holdings here in order to protect from pollution the historic Spot Pond, which furnishes their water-supply, and these, with other water-basins secured, amount altogether to something like 1,000 acres of picturesque land, much of it well wooded. The town of Stoneham has taken Bear Hill, the highest elevation in the Fells, and proposes to take Taylor Mountain, a continuation of the Bear Hill ridge. Finally, the Trustees of Public Reservations have received as their first trust the Virginia Woods, a fine tract of twenty acres, covered with an old growth of Hemlock and White Pine, lying between the Ravine and Wyoming roads that approach Spot Pond from Melrose, and a fund of \$2,000 has been raised by subscription to care for it.

Finally, Mr. Walter Wright, a son of the late Hon. Elizur Wright, who was the father of the Middlesex Fells project, proposes to give for public uses, in accordance with his father's intention, as an experimental forest, a handsome tract, mostly of White Pine, on Pine Hill, in Medford.

Altogether there are between 1,300 and 1,500 acres, out of 4,000 in the entire region, now assured to public use in the Middlesex Fells. What is needed is to connect the various scattered public holdings, make them convenient of access, secure certain important features that still remain pri-

vate property, like the lovely cascades in the easterly margin, and bring all under a uniform system of administration. This can best be done under the proposed metropolitan park administration.

Boston.
Sylvester Baxter.

Colonial Summer-houses.

AMONG other revivals of old-time usages prevalent during this decade it is surprising not to see some creations resembling the old summer-houses, so much used and admired from fifty to one hundred and fifty years ago on many estates in the older-settled portions of our country. As far as I am aware, the restoration of a few remaining old ones has been the only effort made in this way. These structures were what their name implies—houses for summer. Intended for use during warm weather, when artificial heat was not wanted, they were usually built and finished in a manner to correspond with the best rooms in the houses to which they were adjuncts; indeed, they must often have been superior in their ornamentation and furnishings. Chippendale furniture of the purest design and delicate construction found an appropriate setting in some of them, and in the coast towns, when their owners were also ship-owners, they were sometimes furnished with Teak-wood furniture and those wonderfully artistic pieces from India and China, beside which modern importations look so inferior. The Mediterranean countries were also contributors, and decorations in marble and Italian glass could be found. Often there were delicate chandeliers and tall candlesticks, surrounded by still taller glass shades, like those used in the West Indies, for a free circulation of summer air was desired, and the dripping of wax was thus prevented.

Musical parties were a favorite form of entertainment held in these summer-houses, and on other occasions the supper was served in them, when they were brilliantly lighted and decorated. What we call lawn and garden parties were not then in vogue, but ladies' luncheons were often given in the summer-house, and, no doubt, were as enjoyable as any now held. The ladies often used them as morning and reception rooms, and delightful they were for spinning, reading or needlework, or to receive friends apart from the work of the domestic establishment.

The young people and lovers were especially appreciative of their attractions, and many interesting tales could be told of famous people who arranged the important affairs of their lives within these sheltering walls. Before writing upon walls and window-panes had reached its present vulgarity, inscriptions and couplets were often composed in these abodes of summer life. Even the great Washington and his generals are said to have enriched some little panes of glass with their autographs. The practice was a direct continuation from an even earlier time, as it was on the window of a summer-house that Leicester wrote:

Fain would I climb, yet fear I to fall.

And Elizabeth wrote under it:

If thy heart fail thee, climb not at all.

In the hands of less exalted or witty personages, however, the practice soon degenerates into mere scribbling, and it has no good reason for revival or survival.

But there is something to be said, however, in favor of these attractive little structures. They largely occupied the sphere of the present piazza and summer parlor. With the appearance of the modern piazza they went out of fashion, and, to some extent, their office is filled by arbors and rustic shelters, but these belong more properly to somewhat distant and less frequented portions of the grounds. The true summer-house, although often arranged with windows to overlook the beauty of land and water, is an attraction in itself, adapted to highly cultivated and artificial surroundings, even to gardens of small extent.

It is for use as a detached portion of the house rather than an independent structure. It should be retired, but not far distant, and should correspond in architectural features with the main structure. There are some dwellings upon which it is difficult or undesirable to have the usual piazza, especially in mountain districts, where frequent rains make it desirable to have the sunshine directly upon the house, and in foggy situations near the ocean, where dampness makes the piazza objectionable. It is often hard to build an addition to a building already completed, and the problem might be solved and additional room furnished by a disconnected building that would answer every purpose and add to the attraction of many establishments. Afternoon teas and strawberry parties can be delightfully managed from them, and they lend themselves gracefully for all kinds of floral decorations.

The illustrations on page 65 are from examples still remaining in Rhode Island, and show our ancestors' taste, although these are less ornate and smaller than some formerly in existence. They are all of one story, although we have heard of those which had two. They are built of wood, and the workmanship is of a high order. The roof-line in two of them has received careful consideration, and adds much to their picturesqueness. In the third, however, the upper part is inferior in design. This is the one with the flight of steps, and it is built upon a huge boulder in the garden of Wm. B. De Wolf, in Bristol, where it has weathered the memorable gales of 1815 and 1869. A carved figure of an Indian with a tomahawk surmounts the centre of the roof. A figure of a cavalier occupies the same position on the second, which also stands in Bristol, and for many years overlooked the harbor from its position in a terraced garden, which is said to have had great beauty, and situated directly upon the shore of Narragansett Bay. A high carved fence, surmounted with wooden urns, separated the garden from the highway, and other carvings ornamented the grounds, which were of the era when not only Sir Timothy Dexter, but all of New England, admired decorations of this sort. The larger house on the left is in the garden of Mrs. E. S. Diman, now in Providence, but once famous as Rose Farm, with its beautiful grounds. The building is large and commodious, showing the same care in construction and delicate finish as the others, in cornice and other details. The foundation is of cut freestone, and underneath is a well-paved store-room that has been in use for several generations. Our modern architects could doubtless design structures with all the attractions of the old ones, and adapted to the requirements of modern life, if a desire for them was manifested.

New York.

John De Wolf.

Notes of a Summer Journey in Europe.—VI.

THE botanic garden at Leipzig has, within a few years, been removed from its old location to entirely new grounds, so that none of its trees are large. Owing to the limited area they are also much crowded, and can never become finely developed. The collection here is said to contain about six hundred species and varieties of trees and shrubs. As at Munich, it is found impossible to grow good specimens of conifers.

The park called the "Rosenthal" is a pleasant, restful recreation-ground of meadow and woodland, generally free from artificial embellishments, and with no more drive-ways than seem absolutely necessary. Many of the trees in the park have attained to a large size. The European Hornbeam (*Carpinus Betulus*) is here planted with the Common Elm (*Ulmus campestris*), forming fine broad spreading trees, almost equaling the Elms in height, and with trunks two feet in diameter. Among American trees noted were some good Hickories and fine typical specimens of the Pin Oak (*Quercus palustris*), with trunks a foot in diameter. The stems of exposed trees on the streets are protected by coarse basket-work, five or six feet high, which answers very well as a guard and is cheaper and less liable to injure the trees than many more elaborate contrivances.

From Leipzig to the old town of Merseburg, by way of Halle, need not take more than an hour by the railroad, and a brisk walk of an hour and a half from Merseburg brought me to the little village of Zoeschen, where Dr. G. Dieck has established his collections and nurseries. There are some fine avenues of old Horse-chestnuts in Merseburg, and the road to Zoeschen, like most of the roads in this part of the country, is lined on both sides with fruit-trees, principally Cherries, which bear fruit of good quality, but great quantities of Pears, Apples and Plums are also planted. All were bearing heavy crops of fruit, and most of the cherries had already been picked. Sections are sometimes planted in Lindens or other suitable trees. The fruit-trees are planted about twenty-five feet apart, the distance across the road being thirty feet. The country here is flat, with soil too rich and valuable for regular farm-crops to allow much of it being devoted to woodland.

Dr. Dieck has given his establishment the name of "National Arboretum," a title which might easily give a wrong impression of the status and character of the place. It has no connection whatever with the government, being solely the property and enterprise of Dr. Dieck. Besides being a nurseryman and an arboriculturist, Dr. Dieck may be classed as an extreme enthusiast on the subject of trees and shrubs and as a collector of everything that promises to be an addition to his stores. New plants, valuable only for their botanical interest, are collected as eagerly as the showy species, and Dr. Dieck has the reputation of being very generous with his plants to botanical

and other scientific institutions. Collectors are employed in various parts of the continent of Asia, of Japan, of some of the not thoroughly known cooler regions of Europe and North America, wherever it is likely that hardy novelties may be obtained. As the climate of this central German plain is severe in winter, it is the aim of the proprietor of the "National Arboretum" to procure his stocks from the highest latitudes and altitudes or most exposed situations in which they occur in their native habitats. I have spoken of Dr. Dieck's enterprise in collecting, because he is apparently trying to do a work in Germany similar to what the Messrs. Veitch have long been doing, in introducing new plants to English gardens.

The grounds in the immediate vicinity of the house are filled with various trees and shrubs, with small nursery material, and particularly with the newer and rarer acquisitions. An idea of the pains taken in bringing the collections together may be gained by the statement that it is claimed there are about 500 species and natural variations of wild Roses here, and an equal number of forms of Willows. But, besides being torments to systematic botanists, the great majority of these variations or hybrids are of no particular value either for use or ornament. The custom of giving Latinized names to garden-hybrids, or the merest variations, is also to be deplored, as tending to create greater confusion in the nomenclature and synonymy of already well-defined species. An interesting hybrid was one between *Rosa Beggeriana* and *R. rugosa*, which produces rose-colored flowers from the tips of its shoots throughout the season, as is the habit of *R. Beggeriana*. Great pains have also been taken to introduce the kinds of Roses from which attar of roses is produced, and some account of these forms is given in the catalogues.

A shrubby *Polygonum* from Afghanistan may prove to be an interesting addition to our gardens should it be found sufficiently hardy. *Rhododendron Ungerni*, from the mountains of Armenia, is considered another great acquisition, as it gives promise of being quite hardy. The leaves are very white on the under surfaces. One or two other novelties in *Rhododendrons* are also promised. *Hedysarum multijugum*, from Mongolia, is here quite hardy, forming a straggling shrub five feet high. A white-flowered *Cytisus* from the Balkans is much prized.

The raising of *Coniferæ* and *Ericacæ* from seed is not any easier here than we find it in America, as the young seedlings are just as liable to sudden and wholesale destruction by fungi unless great care and watchfulness is exercised. During the first years, or until they have attained to a good size and strength, the young evergreens and plants of the Heath family are sheltered from the direct rays of the sun by very loose mats made of coarse reeds or grasses placed on frames which are sufficiently elevated to admit of free passing beneath.

The main nurseries are divided into several large and quite separate blocks of many acres in extent, perhaps comprising about 125 acres in all. Ornamental, shade and fruit trees are grown. A large portion of the fruit and shade trees produced here are grown with straight clean stems, without branches for six or seven feet or more, to meet the great demand for trees for road-side planting. Among the conifers there were a number of species, generally considered thoroughly hardy in regions much colder, which showed some injury from the frosts of the last winter. Many young Spruces were greatly injured by a species of Spruce-bud louse, probably *Chermes (Adelges) abietis*, which causes cone-like swellings on the tips of the shoots and branchlets. It is the same or a closely allied insect which often attacks and seriously injures Norway, White and other Spruces in our own country. There seems to be no remedy except cutting off the infested tips as soon as they appear and burning them at once, instead of throwing them on the ground, where the insects would probably be able to complete their development. It is noticeable that trees in vigorous health are apparently less affected than those which make poor growths or are in uncongenial situations.

This insect came under my notice in a curious way when on the Rigi, in Switzerland. A great deal of buzzing overhead among the branches of some Spruces proved, on examination, to be caused by swarms of bees, wasps and flies which had been attracted by the liquid excretions or honey-dew made by great numbers of chermes with which the trees were infested.

Between Halle and Berlin the train passes many more large tracts of forest, and here we find the Scotch Pine (*Pinus sylvestris*) chiefly planted. As a rule, only the poorest land is planted in wood, and its poverty is often attested by the White Birches, which spring up among the Pines where there are favorable conditions. The Pines looked in good thrifty condition, and over large tracts the trunk of every one was encir-

led by a band intended to prevent inroads by certain injurious insects.

As would naturally be expected at the capital of the empire, the Botanic Garden at Berlin is one of the best of these German public institutions. Besides the collections of living plants, it has connected with it a very excellent botanical museum, which is open to the public on certain days in the week, and which cannot fail to be almost as instructive as the garden. The collection is especially rich in representing trees and the more useful plants and their products.

Of the plants in the garden it seems hardly necessary to speak in detail, as there is a good deal of similarity, both in arrangement and specimens, in many of these institutions. In naming the specimens the Latin name and authority, the German name and the native country are given on the labels.

The present director has given the Alpine Garden a prominent place here, some fine trees having been sacrificed to it. The trees in the garden are generally rather crowded, but there are some large well-developed specimens among them. A specimen of a form of the Oriental Plane-tree has a trunk approaching five feet in diameter at two or three feet from the ground, and shows no signs of disease.

The Oregon Ash (*Fraxinus Oregana*) was noticed, about twenty-five feet high, growing vigorously and fruiting freely.

The mystery which surrounds the origin of the Myrobalan Plum (*Prunus Myrobalana*) was here recalled by a large broad spreading tree, thirty feet high, labeled under the synonym *Prunus cerasifera*, and with North America credited as its natural habitat. Most horticultural works, as well as other gardens, almost uniformly attribute this species to North America, and it is strange that it has not yet been found wild by American botanists if it is a native of this country.

The evidence seems to point to south-western Asia as its natural home. Seeds, without name, which were sent to the Arboretum by Max Leichtlin, and said to have been collected in Turkistan, produced plants of this species which bore yellow fruit. It is true that this seed may have been wrongly labeled by mistake, or the plants from which the seed was collected may have been introduced and not been indigenous to Turkistan. Another point in favor of the idea that it is a native of Asia is that we have in what is called *Prunus Pissardi* in many nurseries a plant which is evidently a form of the Myrobalan Plum, and already it is to be found in gardens and catalogues under the name of *Prunus cerasifera, foliis purpureis*, or *P. cerasifera, Pissardi*.

Whence this came to Europe is known, for it is recorded that it was first sent to France by Monsieur Pissard from the capital of Persia, the sender being at that time gardener to the Shah.

Seeds of this purple-leaved Plum have been sown and the young plants derived have agreed exactly, in every essential particular, with plants of the true Myrobalan Plum of the same age, the leaves of the seedlings being of the natural green color.

It is to be hoped that Dr. Dieck, Max Leichtlin or some other of the enterprising botanical explorers of south-eastern and central Asia, may soon be enabled to enlighten us as to the true home of the wild Myrobalan Plum.

Arnold Arboretum.

J. G. Jack.

Notes on Cone-bearers of North-west America.—I.

MISNAMED CALIFORNIA PINES.—Two species of Pines belonging to the close-cone group are bearing in our present Pine literature untenable names. I allude to the Monterey Pine and the Narrow-cone Pine, called *Pinus insignis* and *P. tuberculata* respectively. The first was named more than one hundred years ago by one of the earliest botanists to deal with California plants.

PINUS CALIFORNICA, Loiseleur, in *Nouveau Dubamel*, vol. v., 243 (1816), in part, excluding characters of the seeds.

P. tuberculata, D. Don, in *Trans. Linn. Soc.*, xvii., 441 (1837), and

P. radiata, D. Don, l. c. 442.

P. insignis, Douglas, in Loudon's *Arboretum* (1844), and most subsequent authors.

The name conferred by Loiseleur de Longchamp in 1787 (published l. c. in 1816) was accepted by such eminent botanists as Loudon, Endlicher, Hooker & Arnott, Nuttall, Carrière, etc., but was not taken up by most other authors, perhaps on account of an error in the description of the seeds, due to mixing of specimens.

However, under the laws of botanical nomenclature, adopted by the International Congress at Paris, 1867, the Article 49 (with remark under it) requires that Loiseleur's name be restored, inasmuch as he sufficiently distinguished the species, and, fortunately, *Californica* is a very appropriate name for the first-described California Pine.

The treatment of the other species—the Narrow-cone Pine—must be more radical, involving the coining of a new name, *Pinus attenuata*. *P. tuberculata*, Gordon, in *Jour. Hort. Soc., London*, iv., 218 and f. (1844), and subsequent publications.

Mr. Gordon described correctly, and was the first author to do so, the Narrow-cone Pine, which he supposed was the same as the one described from meagre data, and named *P. tuberculata* by Don (l. c.); but that Pine was a small-coned form of the Monterey Pine, as the figure in Lambert's *Pinus*, 1st ed., iii., 131, t. 85, plainly shows, and it is so cited by recent authors, hence the name *tuberculata* was misapplied unintentionally to this abundantly distinct species, which may now bear the name *attenuata*.

Fig. 12.—Colonial Summer-houses.—See page 63.

suggested by the tapering cones as well as the slender habit of the trees when found in groves. † *J. G. Lemmon*.
Oakland, Cal.

[It is possible that the plant described by Loiseleur as *Pinus Californiana* (not *Californica*) may be identical with the species now commonly known as *Pinus insignis*. The fact that the specimen upon which Loiseleur's species was founded was gathered at Monterey points to this conclusion. But the seeds of *Pinus insignis* are not edible, as he represented them, and his description is so unsatisfactory and faulty that it is impossible to recognize absolutely from it the species he intended. Under these circumstances the only safe way is to pass over Loiseleur's name entirely. This was the conclusion reached by Dr. Engelmann (see Brewer & Watson, *Botany of California*, ii., 127), who also discarded as too uncertain the *Pinus adunca* of

Bosc (*Cat. Hort. Paris*, 247), first published in 1816 by Poiret (*Lam. Dict. Suppl.*, iv., 418). The oldest name of whose identity there can be no question is therefore *Pinus tuberculata* of Don, and this, it would seem, must be taken

up in place of the much later *Pinus insignis* of Douglas, although it has, unfortunately, been long associated with another species, the *Pinus tuberculata* of Gordon, now to be known by Mr. Lemmon's name of *Pinus attenuata*.—Ed.]

Foreign Correspondence.

London Letter.

THRINAX MORRISII.—This is a new species of Palm which the Assistant Director at Kew, Mr. Morris, discovered in Anguilla, one of the Leeward Islands, when on a visit there last year. He brought back with him stems, leaves and fruits, from which Herr Wendland has made his description. Subsequently, good seeds were obtained for sowing at Kew. It differs from all other species of the genus, in being of very small stature, rivaling in this respect *Phoenix Roebeleni*, the pigmy Date, which was figured in GARDEN AND FOREST a year or so ago. In the *Kew Bulletin*, for May last year, Mr. Morris stated that :

"Before arriving at Blowing Point (in Anguilla) an interesting little Palm was found growing on broken limestone rocks. It was present in fairly large quantities, and the fan-shaped leaves were used for thatching native huts. The chief interest attached to this Palm is connected with its dwarf habit. The largest and most mature specimen did not measure more than about thirty or thirty-five inches in height, and the stem was about two and a half inches in diameter. . . . There is little doubt it will prove most attractive and interesting in a horticultural sense."

The species of *Thrinax* which finds most favor in England is *T. elegans*, sometimes called *T. Barbadosensis*, sometimes *T. Loddigesii*, but which ought properly to be called *T. radiata*. It forms a pretty pot-plant when small, and when large is one of the handsomest of the smaller fan-Palms, the elegant leaves clothing the stem almost from top to bottom, even in tall specimens. *T. excelsa*, *T. parviflora* and *T. argentea* are also exceedingly handsome. There are splendid specimens of these in the Palm-house at Kew. With reference to the exceptionally dwarf character of *T. Morrisii*, it is just possible that under conditions less exposed and more favorable than those under which Mr. Morris found this species, it may grow much larger than any seen in Anguilla. I know this happens with some kinds of *Phoenix*.

CHILD'S NEW JAPANESE WINEBERRY.—Under this name a plant is advertised, this week, by an American nurseryman in some of the London horticultural journals. It is described as a bush five to seven feet in height, and as being able to "stand alike the cold of northern winters and the heat of tropical summers without the slightest degree of injury." Judging from this description and the picture of the plant which accompanies it in the advertisement, I have no doubt that the plant meant is the Japanese *Rubus phoenicolasius*, which was introduced from Japan into Europe by Dr. Maximowicz. A plant of it was obtained from the Jardin des Plantes, Paris, for Kew in 1875, from which a picture was made and published in the *Botanical Magazine* in 1880 (t. 6479). For the first year the plant at Kew grew outside among the collection of hardy Rubi, where it was nearly killed by the cold of the succeeding winter. It was then removed to a sunny position in the large temperate house, where it grew luxuriantly. Here it assumed the habit of a very tall Raspberry, the shoots growing to a height of ten feet or more. They were fastened to a pole. In summer the plant flowered freely, and the flowers were succeeded by a fine crop of shining scarlet fruit, scarcely as large as an ordinary raspberry. The fruits remained on the plant until midwinter. They were fit to eat, but mawkish and inferior in flavor to blackberries. The flowers are small, the petals pinkish, with long calyx lobes, which fold over the young fruit, expanding again as the berries ripen. The stems, petioles, midrib of the leaf on the under side, together with the flower-stalks and calyx-lobes, are clothed with long, stiff, gland-tipped red-

purple hairs; there are a few spines at the base of the ripened stems. These hairs are, perhaps, the most ornamental feature of this species of *Rubus*, although the fruit, when ripe, is attractive. With regard to the statement that it will "stand the cold of a northern winter without injury," I should say that it depends on what is meant by "northern" and "winter." Certainly the plant is not hardy at Kew, where it is still grown in the temperate house.

[There is no doubt about the ability of this *Rubus* to endure the winter climate of New York and its vicinity. Plants stand out here with no protection, and are perfectly hardy. It is quite possible that the seeds sent to Europe by Dr. Maximowicz came from a more southern region than those from which the strain offered by Mr. Childs were grown. Professor Georgeson collected these seeds in the mountains of northern Japan. It is probable, too, that there is as great a difference in the quality of the fruit of different plants as there is in their hardiness. The berries we have tasted are by no means "mawkish."—Ed.]

CATTLEYA LABIATA VERA.—A somewhat novel method of subscribing to a charitable institution was adopted lately by Messrs. F. Sander & Co., who placed in the hands of an auctioneer a large newly imported specimen plant of this *Cattleya* to be sold for the benefit of the Gardeners' Orphan Fund. The plant was a magnificent one, having over 250 healthy pseudo-bulbs, forming a mass more than a yard through. It realized fifty guineas, a price which, under the circumstances, may be called a fancy one, really good plants of this *Cattleya* being now obtainable in England or Belgium for about five shillings each. Such a specimen as the above would be probably fifty years old at least. Messrs. Sander & Co. have promised to give a full and complete account of the discovery of this *Cattleya* in the forthcoming number of *Reichenbachia*.

The Gardeners' Benevolent Institution was established about fifty years ago for the purpose of assisting aged and infirm gardeners who were unprovided for in any other way. The subscription for gardeners is a guinea a year, but by far the largest proportion of the funds are contributed by wealthy sympathizers. Upward of \$275,000 have been distributed in pensions and gratuities since the institution was started, the sum disbursed last year amounting to \$13,700. While preference is given in the election of pensioners to those who have subscribed, a considerable number of those who enjoy the benefits of the institution have been elected on the recommendation of liberal subscribers. The sum granted per week to each pensioner is four dollars for a man, three dollars for a woman. Last year a pensioner died at the age of 103. He had been in receipt of assistance from this institution for over thirty years. Members who have subscribed one guinea annually for fifteen years are, on attaining a certain age, entitled to a pension without taking their chance in an election. The good work done by an institution of this kind is too apparent to need comment. With this to look after the comfort of the aged gardeners, and an equally zealous and beneficial body of a similar nature—the Gardeners' Orphan Fund Committee—to provide for and educate the orphan children of gardeners, the cause of the needy among those who practice horticulture in England does not go uncared for.

W. H. FITCH.—Any one familiar with the English botanical literature of the last half-century will be acquainted with the name or initials of this botanical artist, who for about forty years was the acknowledged first botanical draughtsman in the world. His death, which occurred at Kew on the 14th instant after an illness of over two years, has served to call attention to the enormous amount of valuable work he did. He was a Scotchman, having been born in Glasgow in 1817, where he was employed as a boy in a printing-house. His early promise as a draughtsman was the means of bringing him to the notice of Sir William Hooker, at that time Professor of Botany at Glasgow University, and young Fitch was engaged by him to assist

him privately. When Sir W. Hooker was appointed Director of Kew, in 1841, he brought Fitch with him. Here he soon found scope for his skill in the preparation of botanical illustrations of all kinds. He made the plate for Hooker's *Icones Plantarum* from the commencement (1837), and soon afterward took over the entire work of plate-drawing for the *Botanical Magazine*, for which he was sole artist for a period extending over forty years. He made the illustrations for all the principal publications prepared at Kew up to within a few years of his death. The splendid folios by Sir Joseph Hooker on Himalayan Plants and Himalayan Rhododendrons; the six quarto volumes which were the result of Sir James Ross's Antarctic expedition; the *Botany of the Herald*; the *Flora Vitiensis*; Bateman's *Odontoglossums*; Elwes' *Monograph of Lilies*; Saunder's *Refugium*; Howard's *Cinchonas*—these contain some of his best work. He also prepared the illustrations for the botany of the Speke and Grant expedition, published in the *Transactions of the Linnean Society*, and for Welwitsch's plants, published in the same periodical. All the numerous pictures of Ferns published by Sir W. Hooker were by Fitch's hand. His fidelity to nature, the judgment he exhibited in bringing into prominence those details which in botany are of primary importance, although art of the popular kind would hide or ignore them; the picturesque arrangement of his subject, the accuracy of outline, perspective and color—these were some of the points in which Fitch excelled. His eight magnificent illustrations of the *Victoria regia*, prepared for the Elephant folio devoted to this plant by Sir William Hooker and published in 1851, are among the best examples of his picturesque work. He obtained a Government pension of £100 a few years ago.

Cultural Department.

New Chrysanthemums.

ONE of the most striking things connected with the present passion for Chrysanthemums is the almost universal passion for change. The fancier may be faithful to the species, but he is certainly very fickle in his attention to individual kinds; and constant and unceasing change in the varieties grown, and not always for the better, seems to be the rule. Amateur cultivators of other flowers, while testing new varieties, will grow the old ones year after year for a lifetime, but looking back for the last decade, there will be found very few Japanese Chrysanthemums in the lists of that time which are now much esteemed or grown, while in this country the most popular varieties are mostly of home production or imported more recently from Japan. The French varieties which preponderated no longer than five years ago are gradually disappearing from the lists, and new ones excite little attention here, except in special cases. American kinds are also making their way in the world at large, though it took the foreigner a remarkably long time to discover their merits. It is scarcely five years since one of the leading English growers and dealers wrote me that he had seen only one good Chrysanthemum from America. To-day they are appearing on the prize-stands, and gain certificates in what seems the most erratic way.

From the lists of new varieties now appearing, it is pleasant to know that the most ardent desire for change can be gratified. I have not counted the number of new varieties offered from various sources, but from a careful estimate I think that a fairly full collection of the new kinds could be secured for something over \$400—not an excessive amount for a fad, but a striking contrast to the condition of things a few years ago. Most interested growers have already made notes of the promising kinds desired, and it is perhaps not expedient to express an opinion as to the merits of the productions of one's neighbors; it may be said, however, that among the new sorts are a fair number of first-rate kinds with a smaller number with striking distinctness. A few changes of color among some older forms seem the greatest gains—as, for instance, yellow hairy kinds, offered by two growers. A form of this character seems to have been first offered in the United States by an Oakland (California) nursery last year under a Japanese name, and W. A. Manda, from the United States Nurseries, is highly commended.

Abroad, Delaux again offers new varieties of his strain of dwarf early-blooming, large-flowering kinds, at prices ranging from one dollar each to two marvels at six dollars each. This last seems an excessive price for a weak Chrysanthemum-slip, but no plant would seem dear with this description: "Nain, 55 centimètres, fleurs soutenues par de véritables liges de fer, cieme frais imitant la cire, flammées et bordées de rose mouseline; coloris frais et entièrement nouveau dans les Chrysanthèmes. Cette nouvelle venue qui est absolument remontante, surpasse en beauté les plus remarquables variétés d'Automne (!) elle fera sensation dans le monde horticole, où elle est appelée au plus grand avenir, pour la confection des corbeilles, culture en pots pour marchés et pots spécimens pour Exposition." Catalogue-writing seems to be one of the things they do better in France. There is an air of sincerity mixed with enthusiasm, and a struggle to express a mental picture in the above which would convert a brazen image into a buyer, or even impress those who have learned to translate into the vernacular by the light of experience.

Delaux's new strain, however, is said to have proved valuable under him in England, and is worth the attention of any one interested in such flowers. The varieties are said to commence to bloom in April, August, September and October, and to be remontant or successional bloomers, and very dwarf, with large flowers. A few of these were exhibited by Mr. J. H. Spaulding last fall in his general collection, being the first shown in the United States. New breaks and types of flowers are always interesting, and in no family more so than in the Chrysanthemum, especially when one has grown a thousand or more varieties, a large number of which are merely slight variations on others.

Elizabeth, N. J.

J. N. Gerard.

Potting Ferns.

THE month of February is generally a good time for this operation, as a majority of Ferns begin their new growth soon after and the roots become active. To secure strong new fronds the Ferns should be potted before the new growth has made much progress, and this is especially necessary when the ball of earth has to be reduced to avoid the use of large pots. With many of the Adiantums this reducing process may be successfully used before the young fronds are far advanced, and at the same time the worst of the old fronds may be removed, although cutting off all the old fronds at this time may weaken the following growth.

Propagation by division of the crowns is best done at this season; but whenever it is possible to secure them, seedlings make better and more rapidly growing plants. Specimens too large to shift without inconvenience are much benefited by a top-dressing of new compost, and the vigor of Tree-ferns will be increased by wrapping sphagnum around the trunk, the moisture thus applied inducing a fresh outgrowth of roots into the moss, and from thence into the soil below. With the *Gleichenias* the dividing process should have been begun before this, the safest practice being to separate the rhizomes some months before the piece is taken away from the parent-plant, thus giving the young Fern a chance to make some fresh roots before the final removal. The potting material for these beautiful Ferns may be somewhat stiffer than is suitable for many others, and especially for the strong-growing species, such as *G. flabellata* and *G. dichotoma*, while *G. Mendeli*, *G. rupestris* and *G. dicarpa* in its various forms prefer a little more peat. But in all cases abundant drainage should be provided, since the plants have shallow roots, and are impatient of stagnant water.

The Filmy Ferns, of which the various *Hymenophyllums* and *Trichomanes* are the best known, will probably need repotting or top-dressing, and the mixture for this purpose should be rather coarse and open in texture, and should include some pieces of charcoal and broken sandstone, or if that is not at hand some broken brick will answer. Ferns of this class, including the lovely *Todea superba*, should be potted rather high—that is, raised a trifle above the rims of the pots—and should not be disturbed about the roots oftener than is absolutely necessary.

In so large a genus as the Adiantums much difference is found in the requirements of the various species, both in soil and in temperature. For instance, the finest of all the Maiden-hairs, *A. Farleyense*, is best potted in a strong soil composed of good fibrous loam, with a small quantity of sand and a liberal proportion of well-rotted cow-manure. Then, with careful shading and watering, it will soon make a fine specimen. The use of peat for this species seems to be a drawback, while for *A. curvatum* I have found nothing better than coarse peat alone. *A. rhodophyllum* and *A. Victoria*, both of which are

very pretty dwarf-growing species, grow well under the treatment recommended for *A. Farleyense*, and, like the latter, are easily multiplied by separating the crowns and keeping the divided plants in a moderately close house and well shaded to induce fresh growth.

All pots used for Ferns should be clean, new pots being preferable, but in case these are not at hand the old ones should be thoroughly scrubbed before they are used for re-potting, not only for the sake of neatness, but for the well-being of the plants.

Holmesburg, Pa.

W. H. Taplin.

Growing Early Strawberries.

THE following plan which I have followed for years will at a moderate outlay bring strawberries a week earlier, and add to their size and quantity. I use a thin muslin, known here as tobacco cloth or plant-bed cloth. This can be bought at about two cents a yard, and it must be thick enough to shade the plants. This cloth should be stretched over the plants early in the spring before the least growth begins. In North Carolina, March 1st is about the right time. No one can expect the Strawberry-plant to do its best unless protected in winter. Here we use pine-needles, covering the ground half an inch deep. As soon as these are removed, and the manure or fertilizer applied and enough straw replaced around the plants to keep the berries clean, the cloth should go on.

After many experiments in search of a cheap and effective way of holding the cloth in place, I use small sticks of riven pine, known here as tobacco sticks, which are about three quarters of an inch square. These sticks are sawed up into stakes fifteen inches long, and sharpened at one end. The other end for about half-way is smoothed with a drawing-knife and a wood rasp if necessary, so as to remove all splinters and irregularities which could tear the cloth. A very small hole is then bored about one inch from the smooth end. Into this hole a section of small, soft wire, say number 17, about six inches long is run and bent around and wrapped on itself so as to hold securely. The other end of the wire is bent either before or after putting in the stake into a hook to hold the cloth. The hook should extend about three inches clear of the stake.

These stakes should now be driven into the ground for about half their length, placing them three feet apart in rows thirty-four inches apart, as some allowance must be made for the shrinking of the cloth, which is a yard wide. Turn the hooks the way the rows run, and let them all point in the same direction.

They are now ready for the cloth. If the hooks set to the east—and I set mine that way as our hardest winds come from the west—begin at the western end of the row. Run the hooks through the selvage of the cloth on each side and lock the outside row of hooks as you go, by twisting the wire around on itself. Leave the inside row of hooks open till you bring up the other width of cloth. Then when the selvage of that is caught on them lock those hooks, leaving what is then the inside row unlocked to hold the cloth on the next trip up. Always go back to the same end to start. When the bed is covered lock the outside row of hooks also.

Your bed is now covered solid with the cloth except for the small gaps along the rows of stakes, and if they are placed in straight rows and driven perpendicular, the gaps will be too small to do any harm. As the cloth is stretched only four inches from the ground and is quite elastic, snow presses it down without tearing it. When the danger from snow is past and the plants about ready to bloom, the covering can by a few minutes' work be raised to quite eight inches from the ground, in this wise: Begin at the end opposite to that on which you began to attach the cloth and bend the soft wire hooks straight upward over the stakes and leave them there. The cloth is so elastic that it can be walked on without injury except very near to a stake.

When the berries ripen remove the cloth, fold and tie it up neatly. Well handled it will last three years. The stakes, pulled up and kept where the hooks will not rust too badly, will last five years.

The benefit of this mode of covering is threefold. It protects from any ordinary late frost, even though the plants may be in full bloom. It hastens the growth and ripening of the berries, bringing them to the table a full week, and in some seasons ten days, earlier. The vines are thrifter thus sheltered, perhaps, because it is the nature of the Strawberry in the wild state to have the protection of weeds and grass, and they bear finer fruit and more of them.

It seems, too, that the distribution of pollen, especially when pistillate are grown with staminate varieties to pollinize them,

is far better under the cloth. As thin as it is, it offers enough resistance to the air to keep the pollen-laden currents of air in great measure near the ground and among the plants.

The original cost of this protection is from three to four cents a square yard. After that it is the mere trouble of putting on and taking off, till the material has to be replaced by new. No thorough-going gardener, after once using it, will ever relapse into the old haphazard manner.

O. W. Blacknall.

Early Peas.

THERE is fortunately no longer any need to waste the space in our home-gardens with the little extra Early Peas so much used by the market-gardeners.

We now have Early Peas of fine quality and productiveness, and dwarf enough in habit to suit the smallest garden. Among these the American Wonder is still unsurpassed in the matter of earliness. Its chief fault is its extremely dwarf character, but this will allow of closer planting and make it desirable for limited grounds. One of the most promising of the new peas is the Chelsea, which we tried last year for the first time. This variety was conspicuous among forty or fifty other sorts for its compact, dwarf habit—about fifteen inches high—and the wonderful profusion of its bearing. The snowy promise of its blossoms, which made the row conspicuous among its fellows, was fully met by the abundant pods. This is the most formidable rival of our old favorite Premium Gem that we have ever yet tried, and it is early with us as Alpha. While here, in North Carolina, these early peas now (January 25th) are being planted a little later than usual, owing to the wet weather. There is still time to consider the question of varieties and modes of culture in more northern gardens.

Peas grow rapidly and complete their growth in a very short time, so give them plenty of readily available food. Even on the richest garden-soil it will pay to give them a send-off with a good dressing of dissolved South Carolina phosphate and sulphate of potash. The mixture should contain eight to ten per cent. of phosphoric acid and six per cent. of potash. A little cotton-seed meal will be of benefit for an early start. The early sowing of Peas should be in a shallow furrow and the soil drawn up in a sharp ridge over the rows, so as to cover them about six inches deep. The ridge lessens the danger of their rotting in too wet soil when sown early, and will warm up earlier than the flat surface. No matter what your latitude, sow the earliest Peas just as soon as you can possibly get the ground in order. They will germinate when only a few degrees above the freezing point, and if not pushed into too rapid a growth by unseasonably warm weather, will stand a hard freeze when once above the ground.

My practice is to sow some of the extra early and early sorts at the first sowing, and then as soon as these begin to appear above the ground sow more of the early sorts, with a selection of late varieties for succession. For earliest planting in the family garden we advise American Wonder, Alpha, Chelsea and Premium Gem. For the second and later sowings a few Premium Gems, and a good lot of Stratagem, Yorkshire Hero, Horsford's Market Garden and the old reliable Blue Imperial.

Most of these are rather dwarf in habit, but all, except American Wonder, will be better for some support, and in a private garden neatness alone requires that they should be kept off the ground. For support there is nothing better than the galvanized wire netting, which we have before recommended. This can be had of various widths, at about half a cent per square foot. I used large quantities of it last year, and the rolls have been kept stored away ready for many future seasons' use. It is cheaper than cutting brush out of one's own woodland as I have proved, and is the neatest trellis that can be had. It is fastened to stout stakes set 16 feet apart in the row. We use the same material for training Tomato-vines.

Raleigh, N. C.

W. F. Massey.

Lithospermum prostratum.—This lovely little rock-plant has not proved quite hardy here. It has endured a few winters, but never seemed to recover from the cold, getting weaker every season, until finally it died. But our rock-garden is in a very exposed situation, without a warm or sheltered nook in it. It is such a favorite with me, however, that I now grow it as a cool greenhouse-plant. Naturally decumbent in habit if grown in a suspended pot, it will hang over on all sides, completely hiding it. The foliage is small, dark green and abundant. The flowers are a bright metallic blue, a color almost characteristic

of the order Boraginaceæ, to which it belongs, and which includes the common Alkanet, the Virginian Cowslip, the Forget-me-not, and other common border-plants, with bright blue flowers, and many plants once commonly used by the old herbalist.

Correspondence.

In the Shore Towns of Massachusetts.—VI.

To the Editor of GARDEN AND FOREST :

Sir,—Mashpee is in some degree an Indian town—Indian enough to be interesting. Before 1834 there was a reservation here, managed by the commonwealth, and the Indians were oppressed and depressed much as Indians usually have been in this country. But since 1834 the people here have constituted a town, with the same organization and relations to the state which other towns possess. These Indian people are poor, and they appear to have more public spirit than the average white people of this country. The town officers are Indians, and the town records are admirably kept. One of the principal Indian men here is a native of Boston, and he has seen much of the world as a sailor. He is a man of broad and varied intelligence and of very substantial intellectual character. He was a Representative in the Massachusetts Legislature some years ago. He resembles in an astonishing degree, in looks, manner and speech, some of the principal chiefs of the Sioux Indians of Dakota with whom I am acquainted. The Indian Town Clerk here is a valuable man in his office. I tried to persuade these Indian people to select a boy having sturdy health, prepare him well and send him to Harvard, and I hope they will yet do this. Mashpee has no holdings for places of public resort. The village is "beautiful for situation" on the shore of Great Pond, a lovely piece of water, with shores wooded nearly all around. A hill on the shore at Mashpee village has a fine grove of Pines, and a dozen acres here would make a beautiful and valuable reserve, but the people are too poor to buy the land, though it would not cost much now. The summer visitors need it already, and will need it more and more. They are only beginning to discover this beautiful region.

The view from the head of the lake, on the road from Sandwich to Mashpee, is of great beauty and interest. Mr. Benjamin Boardley, a colored man who lives here, is a manufacturer of philosophical instruments, and he is also building a steamboat to run on the lake for excursions for the summer business. The three pretty islands in this lake are owned by a company of friends—Mr. Cleveland, Mr. Gilder, the editor of *The Century Magazine*, the two Jeffersons, father and son, and another gentleman. The hotel at Mashpee is one of the best in any shore town.

Falmouth has no public holding except a town-landing, which is not much regarded. I called on Mr. Joseph Fay, who has had much experience in tree-planting. The people in all that country say that he has not only planted thousands of trees himself, but has influenced other men to plant many more. He formerly planted Scotch Pines, but afterward concluded that they are inferior to our native trees for planting in this country. He thinks trees can be made to grow almost anywhere, and that any sea-shore waste in this state can be reclaimed by the methodical planting and care of suitable trees. Mr. Fay has a beautiful Pine-grove of about fifty acres, which he bought many years ago to preserve it. It is an old picnic-ground and much-used public resort. He thinks of offering it to the town or to the Trustees of Public Reservations. Mr. Fay thinks it wrong for towns to yield their public holdings to the attacks of private greed, and regrets the lack of spirit to contend for public rights, as it is this spirit which has built up the structure of protecting laws and institutions for our civilization.

Wareham has no place of public resort. An area large enough for a pleasant green in front of a church is claimed by two men, and the Court adjudged the right to improve it to the two acting together. But as they do not act together it lies waste and unattractive. There are some beautiful White Oaks in Wareham which in form resemble the Live Oaks of Louisiana and Texas.

Marion has beautiful woods along the shores, all private holdings. Mr. Gilder, of *The Century Magazine*, lives here in summer. A great rock, which has a large White Pine growing up through it in a curious way, was about to be broken up, when Mr. Gilder interposed and paid the price asked for the rock. It is thus preserved for the present, and it is an interesting object. A small area of land around it should also be bought, so as to provide for its permanent preservation.

Mattapoisett has two bathing-places on the bay-shore, each perhaps one hundred feet square, four bath-houses and a pavilion. Some years ago the town obtained a special act of the Legislature, authorizing the formation of a park to include the entire water-front of the village—all the land between the main street and the water's edge. The ground was very cheap then, but the plan was opposed by two or three persons and finally abandoned. Now the land has all been taken up by the summer people, and its purchase by the town would be impossible. There is no park or common.

Fairhaven tried about twelve years ago to buy a square for a common, but the project was opposed and relinquished, and there is nothing of the kind in the town except Fort Phoenix, an area of about four acres, to which the national Government holds title. Mr. C. J. Tripp, the custodian of this property, is also chairman of the Committee on Property of the vigorous Town Improvement Association here. He has had charge of the fort about five years, and the trust could not be in better hands. The view from the parapet is of great interest, and from 1,000 to 2,000 people enjoy it daily in warm weather. The association wishes to buy the guns and keep them in place on the walls, but a man on the Hudson wants them for his door-yard. There are five of them, rifled 24-pounders, made at West Point for the Mexican war. The association hopes to acquire title to a bathing-ground on the beach. This society was started to set out trees, but Mr. Henry H. Rogers now buys all the trees needed by the town, and the selectmen plant them. Mr. Rogers is building an extensive library and town hall for the town. There is a cannon at the centre of the village which was captured from the British in the war of the Revolution. An inscription on a bronze plate on the gun recites the main facts in its history. An old Indian burying-ground at Scoticut Neck is now covered by a grove of trees. John Cook, the last survivor of the Pilgrims, is buried in Fairhaven, and the Improvement Association will care for his grave and erect a monument.

New Bedford has a population of 45,000, and a common of seven and three-fourths acres. A drive-way eighty feet wide leads around Clark's Point. The long, winding and very narrow bridge over the Acushnet River, between New Bedford and Fairhaven, is painfully crowded on summer evenings. It offers hardly more than space for the wheel-way. People on foot can barely avoid obstructing the drive, and are in constant danger of being run over by carriages. The dust is suffocating, but the bridge crosses the wide water, and along its course the crowds meet the delicious breath of the sea. It is the only path of escape from the heated city on summer nights, and it should be broadened so as to be a clean and comfortable promenade for the thousands of men, women and children who would seek coolness and refreshment here if there were room for them. It would promote the health, happiness, morality and civilization of the city.

Dartmouth has no public holdings for places of resort, but there are two or three landings at the end of streets or roads. Westport has town-landings on both sides of the river at the head of Westport; their area perhaps four or five acres in all. Part of it is leased to citizens for building purposes. About two acres of land on Horseneck Beach are owned by the town, including a highway, landing and watering-place. There are no commons or parks.

Fall River has two parks—North Park, of fifteen to twenty acres; South Park, sixty acres. There is a public bathing-place, but it is not in good condition, although it might be made so by a breakwater. Leading men here and in New Bedford say that the operatives in the factories appear not to value or use the parks so much as they should. They seem to need some kind of out-of-door amusement or means of entertainment to attract them to the parks. They stay indoors too much, and go to miserable shows in hot, close halls and theatres when they should be in the open air. Is this a new problem, or an old one? It would require time and considerable special observation to ascertain whether the working people of Fall River are less inclined than those of other cities to use and enjoy the public parks. No doubt, the journalists of the city could give us interesting and valuable information on these subjects, and their discussion of them would receive general attention.

I believe there are forty-six of the shore towns and cities of the state named in these notes. Only Newburyport, Manchester, Salem, Lynn, Quincy, Weymouth, Plymouth and Fall River can be regarded as fairly well equipped with parks and commons. Perhaps Essex should be added to this list. Rowley, Marblehead, Hingham, Cohasset and perhaps a few other towns have small commons, but most of the shore towns have no park, common or open space of any kind to which the

people have a right to resort. New Bedford, with 45,000 people, has seven and three-fourths acres of common, nothing besides, and Gloucester, with 25,000 people, has no public area of any kind.

Forests and the Flow of Streams—an Eighteenth Century Opinion.

To the Editor of GARDEN AND FOREST :

Sir,—Much has been written of the influence of forests and their destruction upon the flow of rivers, but in all the literature of the subject there is, perhaps, nothing more curious than the following passage from the *History of the Three Provinces, South Carolina, Georgia and East Florida*, by William Gerard de Braham, Esq., His Majesty's Surveyor-General for the Southern District of North America, reprinted, so far as relates to Georgia, in 1849, by Mr. George Wymberly Jones, from the manuscript preserved in the Library of Harvard College. The author's investigation of the natural features of the Province of Georgia and the adjacent regions extended from 1751 to 1771. The first settlement of Georgia had been made by Governor Oglethorpe in 1732, and Braham tells us that "the Introduction of Sawing, Stamp and grinding Mills was almost as Early as the Settling of the Province; for which Purpose several Streams, Rivers and Rivulets proved very Convenient, but some Rivulets have disappeared two or three years after being chosen, and left the Mills dry, for the following reasons: The Rivulets, as well, as all Rivers and Streams are both sides bordered with large Forests, either low Swamp or high Oak Land, of which the Undertakers of Mills cleared only a small spot of the Trees for the Mill, above which they carried across the Rivulet a Dam, by which the Rivulet overflowed its Shores, and spread its water all over the adjacent lowest Land of the Forrest; the Trees of which (: being Air Plants :) became Subject to the Destruction proceeding from stagnant Water. In short all the Trees perished, their old Roots shrunk from their Barks, and the young Roots with their Barks shrunk from the Earth, so that either between Bark and Root or between Bark and Earth Openings appeared, and the Ground thus perforated became like unto a Sieve, through which the Waters of the Rivulets sunk down to the Quick Sand, where they will continue sinking, until these Passages in course of time are stopt up. This Evil might have been prevented, had they laid out the Land intended to reserve the Mill water into a Field, and planted it for two or three years, and during this time grubbed up all Roots, for which Labour the Crops would have richly rewarded, them (: when the Field overrun with Grass :) had run the Dam across the Rivulet, so they would have kept their Mill water on their old Fields without danger of ever losing it."

F. S.

Meetings of Societies.

The Western New York Horticultural Society.—II.

WE herewith continue the report of this meeting, which was begun last week. The first paper quoted was by Mr. Wm. McMillan, Superintendent of Parks in the city of Buffalo, and it was entitled

OUR AUTUMN FOLIAGE.

It is a well-known fact that the autumn colors of the foliage of American fields and forests are much more brilliant than the tints assumed by the ripening foliage of the woods and waysides of Europe. This notable difference is usually attributed solely to the difference in climate, and more especially to the relatively larger amount of sunshine in America. This explanation may seem reasonable if the comparison be made with the north-westerly half of Europe, where the autumn weather is much cooler and cloudier than here. But the skies of southern Europe are said to be as clear as our own. Near the Mediterranean the autumn days are milder and brighter than in any of our northern and eastern states. Yet the far-famed sunny sky of Spain, of Italy, or of Greece does not color the ripening foliage either on trees or underbrush so strongly or so generally as the American sun does, whether the season here be clear or cloudy. Difference of climate, therefore, cannot be the sole reason, perhaps not the chief one.

There is a common belief that frost is a principal agent in producing the most striking tints, and hence we often hear the remark made that the most highly colored leaves are tinged by frost. This must seem a strange delusion to any one who

watches closely the development of the different shades on the earliest species that ripen long before the first touch of frost. In fact, it may be noted that, as a rule, the brightest tints, whether of red or yellow, and the most extensive display of either, appear during the first half of the season; and the trees and shrubs which turn later show their best hues when the advent of frost is longest delayed. When frost finally comes all foliage susceptible to its touch shows that its action is always to tarnish and never to varnish. Yet it is so easy and natural to reason that autumn leaves are bright-colored because they are frost-bitten, that it is quite probable this will always remain the common belief.

If, then, the influence of frost is always to blur rather than to brighten the foliage, and if also, as is generally conceded, our northern states are subject to the first killing frost at an earlier date than in Europe, the more gorgeous coloring of our autumn woods must seem strangely anomalous if it occur in spite of these disadvantages. I can account for this apparent anomaly only by assuming that it is due to the inherent quality of the plants rather than to the outward action of the elements; in other words, that it is due to the difference in the species most prevalent in each country rather than to difference in climate. Of the species most showy or abundant here, none are indigenous in Europe. Conversely, this explanation is confirmed by observing that most, if not all, of the European trees and shrubs cultivated here show even a less body of color than in their native country. As a general rule, European trees and shrubs grown here retain their foliage much later than American plants of related genera. Consequently, our first frosts come on foliage still partially green, and the effect is to stain or wither rather than to color.

If, then, the high color of our autumn foliage is due to the difference in the species of our trees and shrubs, it may be interesting to note some of the kinds that are brightest or most abundant. It will be seen that the number of species is comparatively few, and that the gorgeous appearance of our forests and fields in autumn is owing rather to the general or extensive distribution of these few kinds. The earliest tree to herald the approach of autumn is the Red Maple. It is closely followed by the Virginia Creeper, the Sour Gum, and the several species of Sumach. All of these assume intense shades of red, and their great abundance makes them everywhere conspicuous. Later, the various shades of yellow appear on the Sugar Maple, the Swamp Ashes, the Small-nut Hickories, Butternut, Tulip-tree, Poplar, Birch, Larch, Spice Bush, Witch-hazel and Yellow Root.

If the season be favorable a considerable body of darker or duller shades of yellow is furnished by the Elm, Beech, Walnut, Chestnut, Basswood, Mountain Ash and Grape-vine. Meanwhile, as the earlier species with reddish leaves drop their foliage, the various shades of red and reddish purple are continued by the Red and the Scarlet Oaks, Sweet Gum, Hornbeam, Shadbush, Hazel, and the several species of Dogwood, Viburnum, Whortleberry and Blackberry. This list is not large, but each species is very widely represented in all our northern woods and by-ways. There are a few other species not so widely distributed that may show on close inspection remarkably bright tints and variegations, such as the Buckeye, Sassafras and Honey Locust, but at a distance these contribute very little to the general display.

We are wont to speak of autumn leaves as being golden, orange, scarlet, crimson, purple, etc., but these terms are rarely accurate on close inspection. When illuminated by sunshine and seen at a favorable distance and angle with the sunbeam, these terms may be appropriate. But on critical examination at close quarters the leaves that showed so clear and pure a tint as the light shone through them or glanced from them, reveal usually a more or less stained mixture of impure shades. In purity or delicacy of tint they will not bear comparison with flowers, nor even with the fresh hues of the opening leaves on some species in the spring.

It must be remembered that the whole display is but a fleeting show—a kind of dissolving view. The duration of the brightest tints is very brief, and to be seen to the best advantage they must be sought and found at exactly the right nick of time. On the most tempting plants a long hunt through the branches may be required before a single leaf is found that is pure or uniform in color, or perfect in form and texture. The outer foliage is usually too much browned or torn by sun and wind, and so the clearest colors and best preserved specimens are more common toward the interior of the tree or bush. This is more noticeable in foliage of any yellow shade than of either red or purple. To develop the latter hues more sunlight is necessary. It is sometimes curious to observe the sharp contrast on the same leaf, when one part of it has been fully

colored in the sunlight, while the other portion, hidden under an overlapping leaf, is still quite green.

Usually each species of tree or shrub assumes the same tints each autumn, varying in degree only according as the season is favorable or not. But some species sport considerably, sometimes being arrayed in orange or parti-colored livery, instead of yellow, or red or purple. The Sugar Maple, the Sassafras, the Buckeye and the Sweet Gum are examples in point, and also the Red Maple, the Shadbush, the Poison Ivy and the Poison Dogwood. Of all our native shrubs this last is surely the most gorgeously arrayed in autumn. The most noxious plant in all our woods may thus be charged with "stealing the livery of Heaven to serve the devil in."

When the Sugar Maple shows a strongly reddish tinge it is a pretty sure indication of starvation or disease. It often happens that some branch is affected while the others are healthy, and thus it will become prematurely and strongly colored while the others are yet green. The leaf of the Sugar Maple is often remarkably veined and variegated, the striping and mottling being sometimes so bold and strong as to resemble the figures on the wings of butterflies. On the same tree or branch leaves of this kind may be found along with others having all shades of yellow or orange or russet.

The White Ash ripens through a curious range of colors unlike any other tree. The green leaf darkens to chocolate and purple, and then turning to violet gradually lightens to brown and yellow. Several of the Oaks have also rare shades of red, russet and tan. As the tissue of all Oak-leaves is too thick to let much sunlight pass through, these colors seem at a distance duller than they appear at short range. Semi-transparent leaves show off to the best advantage in autumn, as the sun-beam makes crimson leaves seem scarlet, russet leaves golden, and lightens every hue in like manner.

Our ornamental plantations make little impression on the general landscape. Of the many trees and shrubs in ordinary cultivation a large proportion are of European origin, and very few are notable for the color of their autumn foliage. As already stated, most of them are harmed by frost in this latitude before the foliage has had time to ripen fully. The Norway Maple is perhaps the most notable exception to the rule. When the season is favorable it fairly rivals its near relative, the Sugar Maple. The Horse-chestnut turns yellow in a favorable season or situation, but its foliage is often prematurely seared by heat or drought or browned by fungi. One other European plant, the Smoke-bush, assumes a strong ruddy tint, showing thus its blood relationship to our Sumachs, a family of plants all notable for the crimson hues of their dying foliage, and also for the various dyes and varnishes and tannic acids obtained by draining their veins after death.

We have in cultivation many trees and shrubs from China and Japan, all of which likewise retain their foliage later than the related species indigenous here. Consequently few of them have the opportunity in this latitude to show the bright colors they occasionally display further south. But the Plum-leaved Spiræa, and the creeper called usually Japanese Ivy, show brilliant shades of red if the season be favorable. The rich variegation and strong contrast of colors exhibited by this so-called Ivy are very striking, because the foliage shows simultaneously every stage of the ripening process from the growing twig to the dropping leaves. Its cousin, the Virginia Creeper, sheds all its foliage a month sooner, its crimson tinge being remarkably strong and uniform over the whole plant. Two foreign coniferous trees, the Larch and the Maiden-hair, that, unlike the Pines, shed their leaves in autumn, change to a bright yellow, and are very conspicuous in a favorable season. Another tree of this family, the Bald Cypress of the southern states, is equally notable for its ruddy tinge.

But the fresh verdure which many foreign plants exhibit, for weeks later than species of the same genera indigenous here, is some compensation for the lack of high color on their immature leaves. This lively and lasting green affords a fine contrast to the autumn coloring of all our native foliage already dying or dead. Some of these plants have a sub-evergreen character, and are but slightly tarnished by frost until perhaps the middle of December, as may be noticed on all the Japanese Privets and Honeysuckles. When finally all the deciduous trees have shed their leaves, the foliage of the evergreen Spruces, Pines and Cedars becomes conspicuous, but generally its aspect is too sombre to be specially attractive, until it becomes heightened by contrast with the snows of winter.

In conclusion, some notice should, perhaps, be taken of the herbaceous foliage of our fields and by-ways in autumn. Strong shades of yellow are common, and some others are reddish purple, most notably the Poke-weed, the strong crimson dyes of which must be familiar to all of you. In our eastern and

northern swamps the Cranberry-vines are often remarkably ruddy, and in the sea-side marshes the Samphire may be seen in autumn in large patches, that attract the eye a long way off by the intense crimson of the leafless stems, which are brighter in color than any foliage of either forest or field.

HOW TO OBTAIN MORE HIGH-GRADE FRUIT.

This subject was treated by Mr. George T. Powell in a practical address, from which we make the following extracts: "We cannot plant young orchards in land from which we have taken continued crops of grain and grass for years, and while the trees are growing continue to take off potatoes, oats and grass for fifteen or twenty years longer, and then hope to secure full crops of good fruit. The trees must be well planted in the first place, with roots pruned back to half their length and the top cut in quite as severely. The branches of a nursery tree are not where they are needed; often two of them are nearly opposite, which will make the tree liable to split apart. Therefore, it is good practice to take off the top entirely, leaving only buds on the main trunk where the future branches are desired. When trees are thus prepared for planting pruning for the next ten years can be done with a pocket-knife, and the fruit and foliage will be where they are needed. Since the foliage plays so important a part in preparing plant-food for use a good growth of leaves should always be ensured. It is of little consequence to use poisons against insects that devour fruit, and fungus diseases which destroy fruit, when the leaves are left to be infested with insects and parasites. Since I have sprayed the foliage of my orchards good Spitzenburgs can be grown once more. Before they were treated in this way these trees set full of fruit, but they never matured into large handsome apples. Healthy wood and healthy foliage are essential to vigorous fruit-buds and perfect fruit. There is a demand abroad, which has never been supplied, for fruit of high quality. In the Old World flavor counts for more than appearance. Every barrel of Ben Davis apples we send abroad depreciates the value of the best American apples."

THE TOXICOLOGY OF THE COPPER COMPOUNDS WHEN APPLIED AS FUNGICIDES.

After considering the chemistry of the copper compounds, the form in which they appear on the grapes, and giving a careful review of the opinions of leading chemists and medical authorities here and abroad, Professor Fairchild gave the following conclusions, based upon his examinations of grapes from the Hudson River district, where the largest amounts of copper were used:

1. The danger from the daily absorption of small quantities of copper salts with foods has been greatly exaggerated. The poisonous nature of such doses is not only not proven, but is denied by eminent authorities, whose views are supported by abundant evidence.

2. Grapes sprayed with the Bordeaux mixture according to the directions of the department in their latest publications cannot possibly contain more than 35,000 of a grain of copper to a pound of grapes in the bunch, which amount is less than one-tenth of the amount contained in a pound of ordinary beef-liver, and absolutely inoffensive to the human system.

3. The insoluble form in which the salt of copper occurs upon the clusters, and the fact that the consumers do not eat the skins nor stems, places the mixture further still from suspicion.

4. The use of a reduced formula for the Bordeaux mixture, containing only two pounds of copper sulphate in place of six, and the substitution of the ordinary ammoniacal solution for the latest treatments immediately before ripening, will place the practice beyond the slightest possible suspicion.

Dr. Van Slyke, who analyzed the grapes from the Hudson River district, from which the grapes causing the trouble in the New York market came, gave the results of his analysis, some of which were not worked out in time to incorporate them in Professor Fairchild's paper.

The amount found on the grapes was very constant, varying from $\frac{1}{125}$ to $\frac{1}{120}$ grain per pound of fruit and stems. Physicians give one-fourth grain doses of copper as a tonic and astringent. Three thousand pounds, stems and all, would have to be eaten to get a dangerous amount of copper. The copper does not occur in the form of sulphate on the fruit, but as carbonate, which is not nearly so soluble.

Notes.

According to the *Dolgeville Herald* there were 300,000,000 feet of timber cut last year in the Adirondack forests. Two-thirds of this was made into lumber and the remainder into

paper-pulp, the product of pulp for the year being about 109,200 tons.

Curiously as it seems to us, the Japanese rank the purple form of the Wistaria high above the white form, and white blossoms of this plant are very seldom used in their floral designs.

An enterprising nurseryman in California offers to send free of charge to the children of every public school in the state a package of plants or a collection of Sweet Peas, if the children will pledge themselves to cultivate the plants within the school-grounds.

It is said that the apple-growers of Albemarle County, Virginia, have lately met a serious loss through the failure of a commission house in Liverpool, to which many of the famous pippins of the region had been consigned. This would seem to be another reason for trying to make a market for these apples in our northern cities.

Two of the new double Lilacs raised by the Messrs. Lemoine are figured in the number of the *Gardeners' Magazine* which has just come to hand. One of these has pure white flowers, each like a little rosette, and is named Madame Lemoine; the other, called Leon Simon, has deep purple flowers, which are very double. Both of them received awards by the Royal Horticultural Society last year.

A correspondent of the *American Florist* speaks of the remarkable absence of hybrid Roses from the flower-markets of this city this year as compared with former winters, when these Roses have been forced in large numbers. An occasional handful of Magna Charta Roses is all that can be seen in this line, and the result is that the only large Rose offered is American Beauty, while Meteor is the only crimson Rose for sale in any quantity, and therefore the supply of these kinds falls very far short of the needs of the market, and they are in very brisk demand. Pink is popular this year, and Madame Cusin, once classed among the most undesirable of cheap Roses, is now a leading favorite, and is sometimes ahead of Catharine Mermet in price. The Bride is still the standard white Rose in this market.

Royal rank is attributed in Japan to three flowers—the Pæony, the Cherry and the Lotus. The Pæony must always be given the position of honor in a chamber on the dais of the principal recess, and may never be placed on a shelf or in any central place; and all other flowers must be excluded from the room adorned by its royal presence. A couple of black, withered twigs are sometimes introduced among the leaves and flowers of Pæonies to enhance by contrast the luxuriant appearance of their leaves and flowers. The Lotus-plant is excluded from festive gatherings because associated with the spirits of the dead, but holds high rank in the art of floral arrangement. It is called the king of Indian flowers, and taste would be grossly violated were it ever combined with the Pæony, which is the royal flower of China, as the Cherry-blossom is of Japan.

Some time ago Colonel A. W. Pearson expressed the fear in our columns that the continuous application of copper compounds to plants as fungicides might result in the accumulation of these salts in the soil in sufficient quantity to cause sterility. In some experiments at the Geneva Station, as reported by Professor S. A. Beach in the *Country Gentleman*, the relatively enormous quantity of two per cent. and five per cent., by weight, of copper sulphate were dissolved and mixed with soil, and plants were grown in this soil. More seeds germinated in the soil treated with copper than in the untreated soil, but the plants were dwarfed, although they matured earlier than the check-plants in untreated soil. Analysis of the top-soil from a potato-field which had received many applications of Paris green, showed about three-ten thousandths of one per cent. of metallic copper. The soil from a field to which Bordeaux mixture had been applied for potato-blight, showed four-ten thousandths of one per cent. of metallic copper, or about sixteen-ten thousandths of one per cent. of copper sulphate. To impregnate such a soil as that which was used in the analysis to the depth of one foot with one per cent. of copper sulphate would require more than 32,000 pounds of the sulphate to the acre, and if applied at the rate of thirty pounds to the acre every year nearly 1,100 years would be required for its application, provided none of the salts escaped in drainage.

Mr. S. D. Dill has lately returned from the Pacific coast, whither he went to secure specimens to complete the Jesup collection in the Museum of Natural History. The most inter-

esting specimen he obtained is a portion of the trunk of a *Sequoia gigantea*, which was sixty-two feet in circumference eight feet above the ground, and ninety feet in circumference at the surface. It is estimated that the tree contains 400,000 feet of lumber, and a piece of the trunk four and a half feet long weighs over thirty tons. The giant stood three hundred feet high, and it was one of a few which still remained of a magnificent grove which is being rapidly converted into lumber. Two mills belonging to the company which own the tract cut 130,000 feet daily during the summer season. On another tract owned by this company there stands a forest of these giant trees containing enough timber to keep their mills running at their present capacity for fifty years. A railroad is to be built to this body of timber to convey the logs to the mill. After the trees are cut down and the logs are cut off it is necessary to split them up with dynamite into quarters before the lumbermen can handle them. Mr. Dill also secured a specimen of *Quercus McDonaldi* from the island of Santa Catalina, although it was formerly thought that this tree grew only on the island of Santa Cruz. *Quercus Morehus*, *Pinus latifolia* (the tree discovered by Dr. Mayr in 1887), *Yucca elata*, *Quercus Engelmanni*, *Q. Palmeri*, *Q. agrifolia*, *Q. Jacobi* and *Populus trichocarpa* were among the other species of which Mr. Dill collected specimens.

A correspondent of the *American Architect and Building News*, writing recently with regard to the World's Fair at Chicago, says: "From an architectural point of view the exhibit from Japan promises to be extremely interesting, and it is hoped that nothing will prevent the execution of the plan. Two acres of the space on the northern portion of the much-sought-after Wooded Island are desired for the exhibition. This sylvan spot was not originally intended to contain any building, and it is somewhat amusing to notice that space for such among its sheltering trees has been demanded by the promoters of nearly every exhibiting scheme. If the two acres are provided in a desirable location there will be erected on them a copy of one of the finest specimens of ancient Japanese architecture extant, and this structure, together with several others equally interesting, will be given to the city of Chicago at the close of the fair as a permanent monument of Japanese architecture and landscape-gardening. The building, it is reported, will be erected at a cost of \$100,000, while the landscape-gardening will be at a cost of \$20,000. One of the other buildings which the Mikado proposes to erect is a reproduction of one at Kioto, a monastery of the Zen sect. Its name is said to indicate the golden pavilion, and its date of construction runs back to 1397. It is surrounded by a garden, with ornamental and small islands designed in the form of tortoises. The pavilion at the water's edge is three stories high, and the interior decorations are said to be brilliant with gilt and coloring. Another building which the Japanese Government proposes erecting is a fac-simile of the so-called Ho-o-do, or Phoenix Hall, a structure that dates back to 1052, and is so shaped as to, in a manner, represent the fabulous bird which is not to be destroyed with fire. There is to be a so-called industrial court, where the different workers of Japan will have their place, and at the entrance a copy of the Yomei Gate of Nikke will be erected."

Florida Pines.

THE picture which appears on another page of this issue (see p. 80) represents a scene familiar enough now to the inhabitants of central and of some parts of northern Florida, and to the thousands who visit the state every winter and spring. A similar scene now meets the eye on the shores of many Florida streams and lakes, from which the original forests of Pine have been pretty generally stripped. On the left of the picture may be seen a specimen of the Long-leaved Pine, so small and stunted that it has escaped the axe of the lumberman and the hatchet of the turpentine-worker. On the right stands a young and vigorous tree of the Pine of tropical America, which botanists call *Pinus Cubensis*. Between the two Pines rises the slender stem of the Palmetto. The young Pines which appear on the two sides of the picture are seedlings of *Pinus Cubensis*, while the ground is covered with the dwarf Saw-leaved Palm, which clothes, with the aid of its spreading root-stocks, the sandy Florida soil as soon as the forest is cut away.

In this picture appear three of the most interesting trees of the American forest. The Palmetto is the most northern in range of really arborescent Palms, a true type of the vegetation of the tropics, and the plant of all others that most delights the northern eye accustomed only to boreal forms of vegetation. The Long-leaved Pine represents the past, and the Cuban Pine the future, of the Pine-belt forests of our extreme southern coast. It is a lamentable fact that the Long-leaved Pine is disappearing and is being replaced by less valuable species. From a time probably long anterior to the arrival of Europeans on this continent the southern Pine-forests have been wasted and abused. First, the Indians burned over the ground on which they grew, to clear away the undergrowth and increase their chances of killing the deer and turkeys which once abounded there. Then the whites, having learned the practice from the Indian, kept up the annual burning

to improve the scanty spring pasturage for their half-starved animals, with the result that these forests, even when the lumberman has not invaded them, stand on ground which is unprotected by undergrowth and from which all the surface humus had been burned away. It is not surprising, therefore, that the trees are far apart and that very few young ones have grown up. These annual burnings have increased in destructiveness year by year for more than a century; and therefore when the lumbermen went into these forests in dead earnest, and began to send the timber they cut from them to the four quarters of the globe, they had a forest to deal with which had lost its recuperative power. When the mature trees were cut away there was no succeeding crop to replace them, and the ground, through repeated burning, had lost the particular quality needed to produce this Pine, and other and far less valuable species replaced it.

More destructive than the squatter's spring fires or the lumberman's axe has been the turpentine-gatherer. For many years the forests of the Cape Fear supplied his demand, but these forests were in time exhausted. Then he began to move south, at first slowly, and then more and more rapidly as overproduction reduced the value of his product and made all but his first year's crop unprofitable. No other commercial enterprise of the civilized world has been so recklessly managed or has produced such meagre profits in proportion to the destruction of the property involved. The cutting into the tree in order to stimulate the flow of its resinous sap, especially if the process is continued through several years, is a serious injury to it; but the injury to the vitality of the tree and to the quality of its timber is a small matter in comparison to the danger of fire, which follows the exposure of resinous surfaces on the trunks of the trees. Three-quarters of all the forests in this country that have been worked for turpentine have afterward been burned to the ground. It seems almost incomprehensible that such wasteful methods can prevail, and yet there are cases on record of a school board in one of the southern states having sold, for twenty-five cents an acre, the right to manufacture turpentine indefinitely on land which they held in trust for educational purposes, and which was carrying five or six thousand feet to the acre of the best pine-timber in the world. The slightest forethought or intelligence, however, would have shown these men that tapping the trees would ruin them. Where such ignorance and indifference prevail, it is not surprising that the forests disappear and agriculture languishes. All these hostile agencies, the axe, the turpentine-tapper, and then the final catastrophe of fire, have worked to the extermination of these forests, which once formed the chief wealth of the southern states, and which as a compact body of available timber of the first quality had no equal in the world.

A part of the territory occupied by this forest, a belt eighty or a hundred miles in width, which extends with a few unimportant breaks from southern Virginia to eastern Texas, will in time degenerate into a wind-swept desert of shifting sand-dunes, which will in time, unless fires can be stopped, gradually spread over the whole territory. In other parts of the region other species of Pines spring up. At the north, that is in Virginia and the Carolinas, the Loblolly or Old Field Pine, of no great worth as a timber tree, is of immense value in the capacity of its seed to generate in burned or sterile soil, and of the young plants to grow rapidly and cover the ground and thus prepare it in time for a more valuable crop. Further south, and especially in middle Florida and in southern Alabama, the Long-leaved Pine is replaced by a more valuable species than the Old Field Pine—the *Pinus Cubensis*, which appears in our illustration. This is the most tropical of the American Pines, and is most at home on the mountains of Honduras and Guatemala, where it forms great forests. It occurs in several of the West India Islands, on the Bahama Keys and on the mainland as far north as the South Carolina coast. Once it was less common in the territory of the United States than it is to-day, for now it is spreading

rapidly and seems destined, in the rotation of forest-crops, to play a not unimportant part in the future of Florida forests. It is one of the most beautiful and symmetrical of all the Pitch Pines, and very showy in midwinter when the great catkins of male flowers hang from the branches. And what is of much more importance, the wood which it produces in Florida is heavy, hard and very strong, and, except in its thicker sap wood and coarser grain, not very inferior to that of the Long-leaved Pine itself, so that if there is anything of promise or of hope in the condition or in the future of our Southern forests, it is that in some favored parts of the country a tree of real value, although inferior to the one it replaces, will probably spread and establish itself until the time when fire shall have destroyed in the soil the elements it requires.

The Yosemite National Park.

IT has become certain that the friends of the great Sierra forest-reservation must unite for its defense against ignorant and short-sighted local combinations. The first struggle, now practically ended, was with the misguided and unhappy Kawean colonists. The impending struggle is partly with the sheep and cattle men who have been stealing pasturage from the national domain, partly with mining speculators, who see possible claims on every barren ledge, partly with lumbermen, who are trying to secure tracts of forest for future use. There are few actual settlers in the high Sierras—there will never be many. The districts that an intelligent public policy would withdraw from sale are almost entirely unfit for farming, and guiltless of the precious metals.

As it always happens in these cases of private greed assaulting public property, the first move is to stir up sympathy for some one or some class. The agitators who have taken the contract to produce such a clamor that the Yosemite Park should be shorn of many thousand acres are anxious to keep in the background. But here and there along the Sierra foothills and in the San Joaquin Valley, we begin to hear of the "hardships of settlers" who "need all the timber." Some of the local newspapers have taken up the cry, and pretty soon it will be in politics.

Mr. Allen Kelly, of the State Forestry Board, who spent last summer in the National Park with the troops, has lately published a very graphic paper upon the subject. His views deserve wide dissemination, to serve as the antidote to falsehoods that enemies of the park are printing. This, for instance, sums up a few of the results:

"Three years ago when Tom Agnew" (an old mountaineer) "came down out of the mountains he counted ninety-two forest-fires on the water-shed of the San Joaquin between his place and Jackass Meadows. The sheep had gone out just ahead of him. Last year there were no sheep in that part of the country, and there was not a single fire.

"In former years it would have been difficult for a company of eleven men with saddle-horses and a pack-train to go through the country on the route that we took, for the reason that they could have found no food for their animals and would have been compelled to pack grain. Last year the grass was plentiful on all the meadows, and camp could be made almost anywhere. Men who live in the mountains say they never before saw so much vegetation late in the season, and the feeling of satisfaction with the results of the exclusion of stock from the reservation is general and deep. The miners of the North Fork and owners of preemption and homestead claims within the park have not found it necessary to stand guard with Winchester over their grass-land, and they have found it possible to go away for a day or two without worrying over the probability that they would find all the feed destroyed by some wandering band of sheep when they returned."

Articles of Mr. Kelly's during the past year in the San Francisco *Examiner* and elsewhere have been characterized by high literary quality and rare capacity of grasping the whole subject. It is a long time since so careful a writer has spent so much time in the field studying such problems. Last summer's work, according to this capable reporter, consisted of one long campaign against the sheep. Captain Wood, an old Arizona Indian-fighter, and Lieutenant Davis, an Oregonian and West Pointer, were the men for the region; they adopted the plan of marching every sheep-herder to the corners of the park, and leaving the sheep to scatter where they chose. This system proved effective, and no other would have done so, for the sheep-men, who were at first treated leniently, kept

driving their flocks back again. Wherever the troops went they saw the results of overpasturing the mountains.

"After entering the country that has been grazing-ground for sheep," Mr. Kelly says, "no game of any kind was to be seen. Deer cannot live where sheep run, because the sheep destroy all the browse; and, moreover, no animal will graze where sheep have fouled the ground. The sheep are driven into the mountains at the time of year when grouse and quail are nesting, and the eggs and chicks of birds that nest near the ground are destroyed by the pattering hoofs of the woolly horde. The high-mountain region is the natural home of the grouse, but in a march of 130 miles only five of the birds were seen.

"It is the testimony of all the mountaineers that before the sheep came into that country game of all kinds was plentiful. Deer were so numerous that a man did not need to leave his cabin-door to get a shot, and grouse could be found anywhere. Hunters have not been numerous enough to kill off the game, and there is no doubt that it has been driven out and destroyed by the sheep."

The evidence that sheep eat off every Fir-shoot within reach, and the young Fir-seedlings, is overwhelming. The ground where they pasture becomes bare and dusty, the young trees die; even the smaller native flora is threatened, and many species are almost extinct. Then come the fires, mostly kindled by herders to burn the underbrush. These fires have done much more damage to the forests than a casual observer would suppose, for the Firs, that constitute a larger part of the older growth, are very easily top-killed. In a few more years they decay and fall. The Fir forests, over thousands of acres of Sierra uplands, are as completely doomed as a North Carolina turpentine-grove after being thoroughly boxed for two or three successive seasons. Other Firs will grow if the sheep are kept out, but the value of the lumber destroyed would buy up every flock in the state of California.

The evidence given by last summer's faithful guardianship of the park contrasts curiously with the heedless clamor of those who regard the system as "an infringement of personal right." The real mountaineers welcomed the troops. When the sheep were driven out game increased, and there was grass for pack-mule, saddle-horse and milch-cow. The real prospectors, wandering lonely and silent through the deep ravines looking for outcroppings, agreed with the rest of the actual mountain-abiders, that the park was a good thing to have. The men of the high Sierra wanted the glory of the forests restored, as they remembered that glory forty years ago. Resolutions against the park came from those who found their free use of national territory at an end, and from discontented and speculative outsiders, mere refugees in the cave of Adullam.

It ought to be easy for the American people to decide the question. Mr. Kelly sums up his report with the remark that "All the timber land in the Sierras now remaining in the hands of the Government should be withdrawn from entry and sale and included in a reservation extending from Shasta to San Bernardino, and the grazing of stock on the reservation should be prohibited and prevented by a patrol of cavalry." This is terse and practicable. It ought to be done by the present Congress.

Winter Rambles in the Pine-barrens.—II.

ONE of the most interesting shrubs of the Pine-barrens is *Shepherdia Canadensis*. The stems are from two to five feet high and clustered like those of the Currant, which it also resembles when covered by red berries in the summer. The compound hairs, formed of many spreading rays united by their edges, coat the buds and smaller branches with rusty scales. They have a roundish outline, with an irregular margin, as some of the rays are free at the end and project beyond the general border. Though the color and abundance of the scales, as a whole, give the bushes a rusty look, parts of them are bright, particularly the buds, which glisten in the sun-light with a metallic lustre. The branches may be gray, or gray interspersed with copper-colored spots, the variations being chiefly due to the color of the bark and the structure and arrangement of the scales; for the rays of the compound hairs are primarily white or pale, and colored only as far as they cohere. When but slightly united at the centre, or when deeply fringed, the grayish brown color prevails, but when nearly or completely united, and the scales compactly placed, we have the bright, metallic lustre. The bark itself is of a dark, reddish brown, and when free from scabs, or visible among those less closely placed, adds to the variety of color.

The winter buds of *Shepherdia* make one of its most attractive features. The plant is dioecious, but it is easy to distinguish the two kinds of flower-buds and the leaf-buds from each other. The leaf-buds are the largest of the three kinds, oblong and terminal or in pairs on the slender branches. The abundant buds of the sterile flowers of pin-head size are globular and clustered. Those of the fertile flower are still smaller, slightly pear-shaped, single or in pairs, and not so crowded as the other. An undeveloped branch often shows the oblong terminal bud with a spherical flower-bud on each side at its base, producing an odd appearance. Their covering and structure are instructive as revealing their adaptation to their winter exposure and early flowering in the spring, for they are well on their way of development. Outwardly they are dry and hard. The rusty scales are so crowded that they overlap or interlock by their jagged edges, making a firm outer case. Being irregular in arrangement, the buds are completely shingled, and their vital parts effectually guarded against cold and rain. There are no bud-scales, the first two leaves to be formed and the calyx of the flower, respectively, serving this purpose in the economy of the plant. The leaves of *Shepherdia* being opposite, two of those just starting unite by their valvate edges, and form a case for the more tender part of the bud within. The cavity is copiously lined with soft white hairs like those on the upper side of the mature leaves. Being close pressed, they further protect the tender part at the base of the cavity with a cottony covering. The flower-buds are made of the four valvate sepals, but are not fleece-lined, the wall of the cavity being green and naked. The bud of the sterile flowers is a hollow sphere, in which a lens shows a circle of stamens, with their yellow anthers already well advanced. In the cavity of the fertile bud the ovary and style, its stigma turned to one side, as in the expanded flower, are easily discerned. Even the single ovule can be removed from the ovary. In both kinds of buds the disk which characterizes the flowers is plainly seen. By comparing the internal structure of the buds with their external appearance the eye soon learns to distinguish the two kinds of bush as readily as when they are covered with flowers or fruit.

Some of the Willows are as easily identified in their leafless state as in the summer. The polished bark of the vigorous shoots makes bright pictures in the winter landscape. Many shades of color, varying from yellows to browns and reds, fairly glitter in bright contrast with almost blackened bark of the old stems. The buds on the young canes are likewise showy with their smooth and shining scales. Though the principal home of the Willow is in the water along the edges of the sloughs, where it contends for the mastery with the Alder and Button-ball, the Pine-barrens have several which are essentially dry-ground shrubs, or flourish on the sand-hills. Among these are *Salix humilis* and the less common *S. tristis*. Both are easily distinguished from other kinds by greenish pubescent branches and their smaller size. On the sand ridges and dunes by the lake-shore the prevailing species are *S. glaucophylla* and *S. adenophylla*. They are from two to six feet high, *S. adenophylla* being the stouter in habit. Both propagate freely by means of their roots and buried stems, the stems quickly taking root and sending up fresh stems, so that the species form extensive clumps crowning the low sand-hillocks. They have a light gray bark, but differ in the color of the young shoots and twigs, those of *S. glaucophylla* being smooth and yellowish, while those of *S. adenophylla* are dark red or purplish. The latter also has the buds and tips of the branches densely pubescent with soft gray appressed hairs, and may be distinguished from all others by this character alone.

The region is rich in species of *Cornus*, all but two of the ten found in the northern states growing here. Three of them are conspicuous for their red or purple bark, and *Cornus alternifolia* is quite as distinct for its deep green stems. The brightest of them is the Red Osier (*C. stolonifera*), its bark being of a beautiful red-purple, so that a clump of it well supplied with young canes is almost crimson at this season. The silky Cornel (*C. sericea*), in the same localities, wears a more sober hue of dull purple. More like the Red Osier is the one recently described as *C. Baileyi*, and figured in *GARDEN AND FOREST*, vol. iii., p. 464. Many of the canes are very bright, and the bark polished, as on the Red Osier. But they are mostly darker colored, being dark red to dull purple, in the latter case more like the Silky Cornel. They differ in color much as does the blood in the arteries and veins. *C. Baileyi* is abundant on the sand-ridge which skirts the shore of Lake Michigan and on the high sand-hills contiguous to it. With the two Willows, *Salix glaucophylla* and *S. adenophylla*, it is the most characteristic shrub of the immediate shore. The three have essentially the same habits of growth, and are well

adapted to the same conditions of soil and moisture. All serve admirably to keep the shifting sands in place, and when met with on the dunes and ridges are likely to crown excrescent knolls and hillocks to whose formation they have mainly contributed by retaining the sand heaped about their roots and stems. As the sand accumulates around their lower parts adventitious roots grow out, and the base of each buried stem or branch becomes the root-system of another stem or multiplicity of stems. In this way they spread with rapidity, and form clumps several feet or yards in diameter. *C. Baileyi* propagates readily in this manner. Its stems are ascending or erect, and from two to six feet high. It does not seem to have proper stolons, like its near ally, *C. stolonifera*, but the analogous provision of spreading by layers, which it also shares with the Red Osier in the sands, serves the same purpose. It would appear to be a desirable shrub to plant in the loose sand by a windy shore to keep it in place, for it serves the same purpose, with the Willows already mentioned, and to some extent the Red Osier, as do grasses like *Calamagrostis arenaria*, and others with long fibrous roots. It thrives in the bleakest situations, and is ornamental at all seasons. With the neat and attractive foliage characteristic of all the Dogwoods, it combines the habit of blooming continuously from June until the frost arrests it, with small cymes of white flowers and clusters of white globular fruit charmingly interspersed among the leaves. It is not difficult to pluck from it a branch small enough for a vase bouquet, with buds, flowers, green and ripe fruit altogether, an unusual character in woody plants in our latitude. In the winter the purple, and frequently shining, stems make it equally ornamental. To what extent it may be distinct from *C. stolonifera* is to me a problem still unsolved, for I have found forms of the latter shrub with leaves and fruit undistinguishable from the type, blooming likewise from June to September, and not merely a second time in late summer or in the fall, a habit with which I have been familiar from boyhood. This may, however, be due to local conditions, the soil in which it grows and the proximity to the lake, but it takes away one character on which I had relied for distinguishing the two species.

Englewood, Chicago, Ill.

E. J. Hill.

Notes of a Summer Journey in Europe.—VII.

IT was my pleasure and good fortune to meet Dr. C. Bolle in Berlin and to visit a number of interesting points under his direction and guidance, and this added greatly to the pleasure and profit of my stay at the capital. One rarely meets such an enthusiast in the study of trees as Dr. Bolle. He is indefatigable in his efforts to secure new things for his own grounds, as well as to procure trees which may be of economic value in Germany.

In his company I visited the newly planned Victoria Park, of which he has the general supervision. The situation comprises an elevated piece of ground, from the summit of which a considerable outlook is obtained. The summit is surmounted by a monumental structure in stone, which, happily, is not a counterfeit old ruin, as are many structures in Continental landscape-architecture.

Large Maples, Planes, Poplars, Elms and Lindens, some individuals with trunks almost a foot in diameter, have been transplanted to this piece of ground with a view to speedily obtaining park-like effects. By care in watering thoroughly and often, and in protecting the bark of the trunks from the heat of the sun, most of the trees appeared to have become well established. It is the intention to plant American Oaks instead of European species, for the curious reason that the former are considered as not so liable to have their foliage eaten by insects.

The trees of the city appeared to have scarcely suffered at all from the attacks of insects during the summer. The Gypsy Moth (*Ocneria dispar*) gives some serious annoyance here at times. About Berlin I found this insect most frequent on Poplars, but the caterpillars, chrysalids, moths or eggs were seen on a variety of trees, and in various parts of Germany, but nowhere in injurious numbers. Being interested in it, from the fact that the Massachusetts Legislature has appropriated such large sums of money for the purpose of suppressing it, I sought information from practical men regarding its ravages and the means taken to lessen them in Germany. It was generally stated that there were no organized public efforts to subdue this pest any more than any other troublesome insect, except the notorious Nonne (*Liparis monacha*), which attacks the coniferous forests, and there is private enterprise and self-interest enough to combat it when locally troublesome.

Although the injuries are some years quite serious, the natural parasites and enemies of the pest usually keep it very fairly in check, so that even if it is unusually plentiful one season the fact does not necessarily mean that it will be relatively more abundant in the year following. It is worth noting that, although the Gypsy Moth was once counted in the insect fauna of England, instead of increasing it has of late apparently become extinct, as it has not been collected on the island for many years.

Visits were made to a number of parks and plantations in the vicinity of Berlin, which are being planted under the direction of Mr. John Booth, one of the proprietors of the once famous Flottbeck nurseries, near Hamburg. Conifers are extensively used, and a decided preference is shown for some of our American species. Great interest and enthusiasm are manifested in the Douglas Spruce (*Pseudotsuga taxifolia*), which does remarkably well here and makes a very fast growth. Some fine specimens were shown, in full-fruit and from forty to fifty feet high. The change of name of this fine tree from *P. Douglasi* to *P. taxifolia* was commented upon; very naturally, it is not liked by those accustomed to the former name, and it will be some time before they become reconciled and accustomed to the corrected nomenclature. In some places *P. taxifolia* was shown as a distinct species from *P. Douglasi*, but, of course, without reason. However, some individuals of the Douglas Spruce are much more glaucous than others.

The Western Hemlock (*Tsuga Mertensiana*) is highly valued here, and great results are anticipated from plantings of Lawson's Cypress. In a sheltered situation and in fairly good soil, some specimens of the latter had attained a height of thirty-five feet in ten or twelve years. A large block of young Catalpa-trees was claimed to be *C. speciosa*, and complaint was made that it was not very hardy, being liable to more or less serious injury in winter. It is not easy to distinguish the two species, especially when young, but an examination of these plants showed that they were probably *C. bignonioides*. It is well known that this is less hardy than the other, although it will do well if not forced into too rapid growth when young, or after it has been established some years and a stem once attains good size by passing through several winters successfully. I was told that the temperature was sometimes as low as twenty-four or twenty-five degrees below zero of Reaumur.

Dr. Bolle's country retreat, known as Scharfenberg, is on an island in Lake Tegel, some miles out of Berlin and not far from Spandau. His estate is thickly stocked with trees and shrubs in large variety, all having been planted within the past twenty-three years. Here the Douglas Spruce is already over fifty feet high, and *Chamæcyparis Nutkænsis* nearly equals it. Another conifer of about the same height is here and in other gardens called *Abies lasiocarpa*, though many botanists consider it merely a geographical form of *A. concolor*. *Libocedrus decurrens* here proves quite hardy and is thirty-five or forty feet high; *Sequoia gigantea* does well, but *S. sempervirens* is liable to be killed in severe winters. The soil is sandy, and, of course, plenty of water is available for the trees.

As Dr. Bolle has, in his letters to GARDEN AND FOREST, given us occasional accounts of his experience and specimens and we may look for more, it is not necessary to speak further of his work now. On the way to his estate a long detour was made on foot to visit the old homestead of Alexander von Humboldt, near the lake. Although the Humboldt family is now nearly extinct, the present occupants keep the place in beautiful order, and it is so secluded and the surroundings are so natural that it is not easy to imagine it as in the midst of a populous country. Some fine avenues of very handsome Lindens are near the house. A tract of woodland in the vicinity had once been planted largely with American trees, and the largest individuals in it now are some fine specimens of the White or Weymouth Pine. This noble tree thrives perfectly in most parts of Germany, yet in many quarters it seems to be in disfavor, and one is surprised not to find it much more common as a timber-tree. In a given number of years it grows much faster and larger than the Scotch Pine, which is so universally planted. The lightness and comparative softness of the wood of the White Pine is considered its chief defect by European growers.

Every one who has heard of the famous Berlin street called Unter den Linden has perhaps pictured it as shaded by an avenue of trees of fine proportions. That, at least, had been my own conception of it, and, therefore, it was quite a surprise and disappointment to find the trees a varied assortment, none over fifty feet high, or with trunks over eighteen inches in diameter. Among them are Horse-chestnuts, Planes, Norway Maples, and occasionally an Elm, the first two kinds of trees

being the largest. Of course, numerically, the Lindens predominate, but none of them have stems over a foot thick, often much less, and the height is in proportion to the size of trunk. The tops have evidently been somewhat cut back from time to time. These trees are said to be very much older than their size would indicate, and their lack of vigor is due to the poor character of the soil. They are apparently well cared for and frequently watered. The Lindens planted here are chiefly what has been called *Tilia vulgaris*, with a few individuals of *T. ulmifolia* among them. *T. vulgaris* is the more attractive of the two, and in general aspect it is between *T. ulmifolia* and *T. platyphylla*, with most resemblance to the latter. That handsome Lindens do grow within the city is shown by some very fine specimens of *T. intermedia* opposite Doctor Bolle's house in the Leipsiger Platz. Other streets in this direction furnish some fine specimens of Horse-chestnuts, Oaks, etc., and in the famous Thiergarten, close by, there is no trouble in getting trees to thrive. Parts of this fine park impressed me as extremely sombre and damp and as though it would be an advantage to let in more light by a thinning out of the trees where greatly crowded together.

New or Little-known Plants.

Begonia Baumanni.

THIS new species, for the introduction of which we are indebted to Messrs. Lemoine, of Nancy, was one of the notable new plants of last year. The plant, well represented on page 77, will not only commend itself to growers of choice flowers by its grace of form and the beauty of its flower, but also for their distinctness of fragrance. Occasionally a slight fragrance has been observed among some of the tuberous Begonias, notably in *B. Maritani*, but it is usually only a suspicion. *B. Baumanni*, on the contrary, has a distinct pronounced Tea rose-like odor, which will not only make the species valuable to the growers, but offers possibilities of crosses with the large-flowered hybrids, which will enhance their value, especially for conservatory decoration. The Messrs. Lemoine recommend that this species should be grown in the open in full sunlight, in which position they are said to grow more sturdily. The flowers have already been described in GARDEN AND FOREST.

Messrs. Lemoine, this season, offer a new fragrant species, *B. fulgens*, which was discovered in the same locality as *B. Baumanni*, in the mountainous regions of Bolivia, near the Peruvian border. The flowers of this species are said to have a Tea rose-fragrance, and to be of a deep strawberry-red.

Elizabeth, N. J.

J. N. G.

New Orchids.

EPIDENDRUM PUSILLUM, Rolfe.—This is a small Brazilian species which has recently flowered in cultivation. It belongs to the section *Encyclium*, and in some respects is allied to *E. Tampense*, Lindl., a native of Florida, though much smaller, as it is only about five or six inches high. The sepals and petals are light green, irregularly freckled with light brown, the side lobes of the lip very pale green, and the front lobe pink, with some paler radiating lines.—*Gardeners' Chronicle*, December 5th, p. 669.

APPENDICULA PEYERIANA, Kranzlin.—A species introduced by Monsieur Peyer, from Sumatra, and flowered by Monsieur Ortgies, of the Botanical Garden at Zurich, Switzerland. It is a small *Dendrobium*-like plant, with long drooping branches, and two or three little white flowers enclosed in white bracts at the apex of the branches.—*Gardeners' Chronicle*, December 5th, p. 669.

ODONTOGLOSSUM × COOKIANUM, Rolfe.—A handsome natural hybrid which appeared with M. S. Cooke, Esq., of Kingston Hill, Surrey. It was received as *O. blandum*, which, however, is very different. The flowers are stellate, the sepals and petals deep yellow with smallish deep chestnut blotches, and the lip white, with a large bright chestnut blotch in front of the crest, and a few smaller ones near the margin. The sharp contrast of colors is

very striking. The lip is very similar to *O. Sanderianum* in shape, which species, or *O. blandum*, may have been one of the parents. As to the other, the deep yellow sepals and petals suggest *O. triumphans* or an allied species. It received an award of merit from the Royal Horticultural Society on November 14th last.—*Gardeners' Chronicle*, December 12th, p. 696.

MORMODES PUNCTATUM, Rolfe.—A new species of unknown origin which has recently flowered with Monsieur Gustav

glance. The segments are narrower than in the former, though otherwise similar, with the lip and column wings rather nearer to *O. Lindleyanum*. The flowers are yellow, with deep chestnut blotches, and bear a certain resemblance to those of *O. × Coradinei*, though more brilliantly colored.—*Gardeners' Chronicle*, December 19th, p. 728.

HABENARIA CARNEA.—A charming little species which has recently flowered in the Royal Gardens, Kew. It is a native of Penang, and was discovered by Mr. C. Curtis, of

Fig. 13.—*Begonia Baumanni*.—See page 76.

Bral, of Mont St. Amand, Gand, Belgium. The sepals and petals are light yellowish brown, densely spotted with very dark brown, and the lip yellow with numerous small chestnut spots. It is allied to *M. Wendlandii*, Rchb. f., but with broader segments and other differences.—*Gardeners' Chronicle*, December 12th, p. 696.

ODONTOGLOSSUM × GODSEFFIANUM, Rolfe.—A handsome natural hybrid which appeared with Messrs. F. Sander & Co., of St. Albans. Its parents are evidently *O. triumphans* and *O. Lindleyanum*, whose characters are apparent at a

the Forest Department there. The leaves are deep olive-green, regularly spotted with white, thus making a very elegant contrast. The flowers are large, the lip white with a long light brown spur, and the other segments of a soft blush-pink.—*GARDEN AND FOREST*, October 14th, pp. 484, 487, fig. 76; *Gardeners' Chronicle*, December 19th, p. 729, fig. 105.

ODONTOGLOSSUM × IMSCHOOTIANUM, Rolfe.—A very interesting *Odontoglossum* which appeared in the collection of Monsieur Vanims-choot, of Mont St. Amand, Gand, Bel-

gium. It appears to be a natural hybrid between *O. Lindleyanum* and *O. tripudians*, as it is quite intermediate in character. It is much like the former in general character, except that the markings are rather more purple in color, but the lip is broader, and the crest and markings are more nearly as in *O. tripudians*. These two species are known to grow together, and the discovery of a hybrid between them is very interesting.—*Gardeners' Chronicle*, December 26th, p. 758.

Kew.

R. A. Rolfe.

Foreign Correspondence.

Bomareas.

THE genus *Bomarea* is closely allied to *Alstroemeria*, and is composed of about seventy species, all natives of high altitudes in Mexico and South America. They have usually long, slender, twining stems, clothed with ovate or lanceolate bright green leaves, with short, twisted petioles; the flowers are borne in terminal umbels and are generally large and bright in color. The root-stock is like that of a *Lapageria*, but the roots have the peculiar character of developing fleshy potato-like tubers, which appear to serve the purpose of food-reservoirs, as they have no buds, and are therefore valueless for purposes of propagation. The tubers of *B. edulis* are said to be eaten in St. Domingo like the tubers of the Jerusalem Artichoke, and those of *B. Shuttleworthii* are greedily eaten by pigs. The stems are usually annual, always perishing after they have once flowered, in this respect resembling the stems of *Liliums*. If the tip of the young shoot is broken, it will not break into growth again. The flowers remain fresh on the plants several weeks, and are developed at all seasons. Seeds are ripened by cultivated plants. The fruits are ornamental, especially after they burst open and reveal the bright red seeds.

Bomareas were not known as garden-plants in England until about fifteen years ago, when Mr. W. Bull, of Chelsea, introduced the handsome species now most generally grown and which was named after his collector, Mr. Cardis. Several were, however, cultivated in botanical collections long before this, *B. edulis* having flowered at Kew in 1814, when it was figured in the *Botanical Magazine*, at t. 1613, under the name of *Alstroemeria*. *B. Salsilla* also was grown at Kew in 1834. Dean Herbert writes as though he had grown some species of *Bomarea*, for he states in his *Amaryllidaceæ*: "They will be found to thrive best out-of-doors in this country in summer-time, and will endure the winter if planted pretty deep in light soil and covered over with leaves in the cold season, especially if any sloped heading be laid on to throw off the wet. Even *B. acutifolia*, which in the greenhouse keeps its leaves through the winter, will succeed with that treatment."

It is difficult to reconcile this statement with actual experience in the cultivation of *Bomareas* at Kew. Here they are grown in a large sunny house, which is devoted chiefly to succulents, the *Bomareas* occupying a raised bed at the side of the house, their stems being trained against the roof-glass. They are never shaded, and the temperature of the house seldom falls below fifty degrees in winter; in summer it often gets very warm. Under these conditions *Bomareas* thrive satisfactorily, some of them being in flower at all times of the year.

A few years ago a duplicate set was planted outside in a sunny south border and treated exactly as recommended by Herbert, but, notwithstanding protection during cold weather, not one of the species survived the winter. Another set was tried three years ago in the temperate house, strong plants being placed in the borders; but whether they were too far from the glass or the soil in the border was too damp for them they did not flourish, and had to be removed to more congenial quarters.

These experiments go to prove that *Bomareas* cannot be grown out-of-doors at Kew, and that they do best when planted in an elevated border in a warm sunny green-

house. The soil used for them is a mixture of equal portions of peat and loam with a little sand. This is placed over a thick layer of drainage. In summer the soil is watered copiously, but only rarely in winter.

Bomareas are propagated by means of seeds or by division of the root-stock in spring. It will be seen from the following descriptions of the species at present cultivated in England that these plants are possessed of qualities such as ought to gain favor for them in all gardens where greenhouse-plants are grown:

B. Caldasiana produces numerous stems annually, which grow to a length of about eight feet in a few weeks. The leaves are oblong acute, dark green above, paler below; the flowers are in umbels of from twenty to fifty, and they are an inch and a half long, the outer segments orange-red, the inner bright orange, with red-brown spots. This plant flowers all through the summer, and frequently all winter. It is in bloom at Kew now. It was introduced into England by Messrs. Veitch in 1865 from New Granada.

B. Carderi, when well grown, is one of the most magnificent climbers. Its stems are as thick as a goose-quill, twelve feet long, clothed with broad ovate leaves, and terminated by compound umbels as much as two feet in diameter, and formed of about forty flowers, which are almost as large as those of *Lapageria*. The outer segments are rose-colored, spotted with brown near the tips, the inner nearly white, with larger purple-brown spots. The umbels of flowers produced a few years ago at Kew and in the Pendell Court Gardens were a great attraction for several months. This species was introduced from New Granada by Mr. Bull and Kew simultaneously. It was at first called *B. Jacquesiana*. There does not appear to be much difference between this and *B. Williamsæ*. Young plants of *B. Carderi* have much narrower and thinner leaves than those of mature robust plants. This species flowers in about three years from seed.

B. edulis, according to Mr. Baker, is the commonest species in a wild state. It has many synonyms, owing, no doubt, to its variable character. It is the only one that has thriven in the temperate house at Kew, where it climbs up a pole to the height of twelve feet, and flowers freely all summer. The umbels are compound, and bear from twenty to forty flowers, which are an inch long, with equal segments, colored yellowish green, copiously spotted with claret-brown. The variety *Chontalensis*, which is figured as a species in *Botanical Magazine* (t. 5927), has larger, brighter-colored flowers.

B. frondea is a recent introduction, having been described and figured by Dr. Masters in the *Gardeners' Chronicle* from a plant flowered by Mr. Shuttleworth in 1882. It is now flowering freely at Kew. In habit and foliage it is not unlike *B. Caldasiana*, but the leaves are longer and Bamboo-like. The umbels are simple, and formed of from twenty to thirty flowers nearly two inches long, the outer segments half an inch shorter than the inner. The color is rich orange-yellow, with a few crimson spots and a tinge of red-brown on the outer segments, the inner being tipped with bright green. It is a handsomer plant even than *B. Caldasiana*.

B. oligantha was imported from Peru by Max Leichtlin and flowered by him at Baden Baden in 1877, when it was named and described by Mr. Baker. It is similar to *B. Caldasiana* in stem and leaf-characters and in its perpetual-flowering disposition. The flowers are one and a half inches long, the segments equal in length, the outer colored orange-red, the inner yellow with red-brown spots. The fruits are as large as a hazel-nut, much wrinkled, and, when they split open exposing the crimson seeds, they are as attractive as flowers.

B. Patacensis was introduced into cultivation by Mr. Shuttleworth from Patacocha, on the western declivity of the Andes of New Granada, and flowered by him in 1881, when it was described by Dr. Masters under the name of *B. conferta*, Benth. This name, however, proved to be a synonym of the above, as was pointed out in the *Botan-*

ical Magazine under t. 6692, where the plant is figured. Its stems, as grown at Kew, were from fifteen to twenty feet long, thickly clothed with leaves five inches long by one in width. The umbels, which are simple, are composed of from thirty to fifty flowers, each two and a half inches long and colored bright crimson, with bluish anthers. The Kew plant flowered in winter, but in the collection of Mr. Chamberlain, at Birmingham, it was in bloom almost the whole year round.

B. Salsilla is sometimes grown in the open border in the extreme south of England. It has rather small flowers on loose compound umbels, their color being mauve-purple. The stems are from three to eight feet long. It is figured in the *Botanical Magazine* as *Alstrœmeria oculata*, and is called B. *oculata* in some gardens. B. *Shuttleworthii* has broad leaves and yellow and orange-red flowers two inches long, with perianth segments equal in length. It was introduced in 1882, but I have never seen it in flower. Others which have been noted as garden-plants are B. *multiflora*, B. *vitellina* and B. *Kalbreyeri*. This last, according to Mr. Baker, is doubtfully distinct from B. *Caldasiana*. It is now in bud at Kew.

Cultural Department.

Five New Bulbous Plants.

THE bulbs of the plants referred to, three *Lachenalias* and two *Freesias*, were procured last summer, potted about September 18th, and have all flowered.

Lachenalia pendula superba is apparently only a fine seedling form of *L. pendula*. Its flowers are of the same colors—carmine, purple and green—and have the same drooping position, which gives the species its name, but they are very much larger than those of the type, both in length and breadth; some of the lower flowers were an inch and three-quarters long, while the upper ones were as large as the largest of the old variety. The flower-stalk was fifteen inches tall, and the leaves very long, broad and fleshy. The name *Superba* is worthily bestowed. It is to be regretted that the same adjective is applied to a variety of *L. tricolor*; there is too much confusion already in the nomenclature of *Lachenalias*.

L. Regeliana is undoubtedly a hybrid between *L. reflexa* and *L. tricolor aurea*, as the vendor states. Its flower-stalk is about twelve inches high, green, blotched with purple, the upper third all purple. The flowers of the main spike were about eighteen, of a rich deep yellow, except that the upper sepal is tipped with green. They incline somewhat upward, and the three upper segments are somewhat longer than the lower. In size they almost equal those of the variety *Superba*; they straggle along the stalk a little more than I wish they did. This is the most satisfactory among the *Lachenalias* in the quantity of its flowers. The bulb, not larger than a pigeon's-egg, gave seven flower-stalks and not less than eighty blossoms.

L. Comesii is evidently raised from *L. reflexa* and *L. quadricolor*, which is, I believe, a variety of *tricolor*. It is very pretty, but not equal to *L. Regeliana*. My bulb gave five flower-stalks, bearing from four to nine blossoms each. These are curved, about an inch and a half long, and stand out nearly horizontally from the stalk. Their general color is lemon-yellow. The three outer segments are somewhat shorter than the inner ones, and are tipped with green; the inner are tipped with crimson-lake. The coloration is derived from *L. quadricolor*, the position of the flowers from *L. reflexa*. This variety is interesting because it shows its parentage so plainly, but it can hardly take rank as an improvement upon many existing kinds. There is no doubt, however, as to the desirability of the two other varieties.

Freesia refracta purpurescens bears a flower as broad as it is long, of the same yellow tint as *F. Leichtliniana*. The outside of lobes and tube is very deeply stained with purple, and three of its segments are marked on the inside with large orange blotches of a very deep, strong shade. The general appearance of the flower is peculiar, and not entirely pleasing; it has, however, the delightful fragrance which we associate with the genus. The plant is very robust, the leaves about an inch broad, the flower-stem about twelve inches high, erect, rigid and branching, and, on the whole, hardly desirable, in my judgment.

Freesia odorata lilacina is declared by its originator to be "a delicate sky-blue or lilac" flower, provided it be grown in the open air. As seen in greenhouse culture I find its color not

much unlike the ordinary white form so extensively grown, for that sometimes shows nearly as much purple, externally, as this. The new variety has other good qualities worthy of notice. The flower-tube is less slender than in the common variety, and its lobes are much broader; the whole flower has much more substance, and appears whiter and more waxy, but its chief superiority is in its sturdiness. Its foliage is upright and strong; its freely-branching flower-stalk is twenty inches high and rigid enough to withstand heavy syringing. I think it a decided gain to horticulture.

Canton, Mass.

W. E. Endicott.

Perennial Plants from Seed.

FOR those who have greenhouses the time for seed-sowing is at hand, and a choice must be made at once of the plants upon which we are to rely for the display of the coming season. It may be a trifle early for many annuals, but all perennials of hardy kinds should now be sown if the convenience of a glass-house and a night temperature of fifty degrees can be provided. If their seed is sown now, most hardy perennials will flower this year like annuals, and will be in a way to give much better results another year.

The proper method of sowing seeds has been often described in GARDEN AND FOREST, but there are minor details concerning which some caution and counsel may be acceptable to amateurs who wish to raise their own plants. Some persons may question the wisdom of going to the trouble to sow seeds when a plant can be obtained as cheaply as a packet of seed, and all the trouble incident to raising the plants avoided. I can only reply that a true lover of plants enjoys such difficulties and uncertainties as challenge his patience and skill. But there are some plants which do not produce seed. *Veronica longifolia subsessilis*, *Dicentra spectabilis*, *Lychnis viscaria splendens*, the double *Lychnis Chalcedonica* and *Lychnis vespertina* are cases in point. The three last named are double-flowered forms, and the reason is plain, but in the two first named plants it is not so easy to understand why seed is never produced here. *Dicentra eximia* yields abundant seed at home, in Tennessee, but very seldom in New Jersey, while here again it seeds abundantly. The flowers of *Dicentra* have to be punctured by bees to obtain the nectar within, and perhaps the agency of various insects may explain this case.

Among the plants that may be sown now to flower the first year are most of the *Coreopsis*, many *Campanulas*, *Centaurea montana*, *Scabiosa Caucasicum*, *Delphiniums* of the formosum and grandiflorum type, including all garden forms, *Doronicums*, *Dracocephalums*, *Echinacea purpurea*, *Globularia trichosantha*, *Kniphofias*, *Linum perenne*, *Lathyrus latifolius*, *Lychnis Chalcedonica*, *L. Haageana*, *Platycodon Mariesii*, *P. grandiflorum*, *Polemoniums*, *Primula auricula*, *Pyrethrum uliginosum*, *P. roseum*, and the double-flowered forms. Of the kinds that will make good plants this season to flower well the next are *Aquilegias*, *Aconitum*, *Agrostemma*, *Dianthus*, *Dicentra*, *Echinops*, *Geums*, *Gypsophilas*, *Helenium*, *Hoopesii*, *Heuchera sanguinea*, *Lobelia cardinalis*, *Morina longifolia*, *Pentstemons*, *Saponaria ocymoides*, *Thermopsis Caroliniana*, *Statice latifolia* and other varieties, *Asphodelus luteus* and *A. albus*, *Primula rosea*, *P. Japonica*, *P. Sieboldii* and the perennial *Lupins*. There are some kinds that require special treatment, such as freezing, to induce them to germinate well, and it is not wise to sow any seeds of these kinds now; if sown in September many months of care and attention is avoided. *Trollius*, *Hellebores*, *Gillenia trifoliata*, *Anthericum liliastrum* and its variety, major, are all better after freezing. *Aquilegia cœrulea*, the beautiful Rocky Mountain Columbine, often comes poorly from seed, and it is necessary to sow every year a little seed, as the plant is a poor perennial; of one hundred plants about seventy-five will prove biennial, or die during the first winter. The seeds germinate better after freezing, but are very difficult to obtain true, and any one who is in a position to collect seed from wild plants would obtain speedy sale for it both here and in Europe. It is difficult to understand the lack of vigor in *A. cœrulea*, while *A. chrysantha*, which occurs in the same region, is the most vigorous Columbine we have. These two *Aquilegias*, with *A. Canadensis*, occur together in a wild state, but never or rarely mix, because there is a month's difference in time of flowering, but when they are planted in gardens near European kinds their individuality speedily becomes lost if they are perpetuated by home-saved seed. Many of us are still hoping for the re-introduction into cultivation of the rare *A. longissima*, figured in an early number of GARDEN AND FOREST. *Dictamnus Fraxinella* seeds freely, and should be sown directly it is ripe and placed in a shady place away from frost, when it will germinate in the spring following, and the same is true of all the *Alstrœmerias*, though these latter

when purchased are often old, and then sometimes take longer than one year to germinate. I have never been able to determine the exact rule of their conduct. Sometimes the seeds germinate freely when not freshly gathered, but oftener the reverse is true. Seed of *A. aurantiaca* gathered last fall and sown at once is now coming up nicely, while purchased seed sown a year ago is only just appearing. *Romneya Coulteri* is a plant that has puzzled many who have tried to raise it from seed; but a correspondent in California writes that it will not germinate until two years after sowing, whether the seed be fresh or not. I have from the same source seeds, both old and new, sowed in the same box, hoping to test the matter.

If seeds sometimes fail it is not always the fault of the dealer, but the lack of knowing just how to treat them. Very small seeds, such as those of *Campanula Carpatica*, are good, as a rule, for one year only, and will not grow when kept longer. They seem to become moldy in the moist atmosphere of dog-days. There is always abundant room for study in the matter of seed and seed-sowing, and the more one learns with regard

than a quite dry one. I have apples stored in a cellar into which an elbow from the furnace projects, and last year the fruit shriveled. This year the graveled floor is sprinkled once a day with water, and the result is very favorable. My apples are neither drying nor decaying. Those who store fruit are also aware that when the cellar is opened in spring to a full circulation of outside air the decay is much hastened. An equable temperature, as conditions allow, should be maintained. In city cellars fruit is more often lost on account of dryness than heat, and I recommend the sprinkling process.

By all odds the best place for storage is in bins about twenty inches deep, suspended along the middle of the cellar in two tiers. Barrels cannot so easily be looked over. There is a prevailing opinion that apples had better not be picked over or disturbed during the winter. This, of course, involves the waste of all partly decayed fruit. Stored in bins apples can be handled as often as necessary, if care is taken not to break rotting ones and get the sound ones infected by the decay. There really ought to be little loss from a cellar full of fruit. As fast

Fig. 14.—Florida Pines.—See page 73.

to perennials the more learning seems to be at fault. In old times, if seeds failed to grow, we used to blame the dealer, and the matter was settled, but sometimes after throwing out the pans a few seed that chanced to be washed over begin to grow, and then we wonder why.

Any one with a garden loses half its charm if he does not grow plants from seeds and watch them develop. Our best Orchid-growers say buy newly imported plants. You have to wait longer to see them flower, but you have the pleasure of doing your own selecting, and so it is with all plants raised from seed, whether they are annuals, perennials, tender or hardy.

South Lancaster, Mass.

O. O.

Late-keeping Apples.

NONE of our apples will resist peculiarly unfavorable conditions. An equable temperature is better than a low temperature. It is particularly unfortunate to store fruit in a drying atmosphere. A moist cellar, not really moldy, is better

as decay begins the waste should go to horses and cows—much to their advantage. I have stored over one hundred bushels this winter, and shall use, not lose, every bushel.

With these precautions, what sorts of apples are our best keepers? The Hubbardston and Belmont and Snow are not all gone before January, but they are of little value after that time. The Spitzenberg may be counted as a January apple. Pound Sweet will keep till April, but is not a good apple after December, besides needing constant watching. The Wagner is in its prime in January, and so is the Spy, but both will keep until April. The Greening has the happy power of holding its flavor until very late. The Kirkland, a native of this section, a seedling of the Bellefleur, is good for nothing before January, and at its best in March and April. The Jonathan holds its own until April—a small but most delicious fruit—a seedling of the Spitzenberg. Seek-no-further is excellent until March, and keeps easily. The Black Gillifleur is finest in January and February, but keeps into March. Baldwin keeps till April, and holds its flavor well. An occasional King will be in condition

till midwinter, but with me the end of them is, or ought to be, in January. The Roxbury Russet is better and better from January 1st until May. The Belle Bonne, sweet, is a superb fruit through January, February and March. The Ladies' Sweeting I do not value, but it keeps admirably till May. Grimes' Golden keeps well till April, a fairly good fruit. White Pippin keeps easily till April, and is a good late apple, handsome, smooth and large. Ben Davis keeps easily till April, but so will cobbler-stones. Tolman's Sweet keeps without trouble till March, but I cannot see that it deserves a place with Belle Bonne. Swaar holds out till May, and in good flavor all the time.

If I were to make out a list of best very long-keepers I would take Greening, Northern Spy, Kirkland, Jonathan, Seek-nofurther, Roxbury Russet, Swaar, Wagner, Belle Bonne. This list I hold to include all the best qualities until the last, and to give as little trouble as any. The Wagners are too delicious to be left out, but are not quite the latest keepers, counting retention of flavor. Those who are fond of Gillifleur may add that. The best baking apple in the list is the Roxbury Russet. My list is made out for the latitude of Boston and central New York, northern Ohio and the north-west. Farther south most of these apples mature earlier, and are not late-keepers.

Tomatoes.

EVERY gardener knows that in the past thirty years a great advance has been made in the general quality of our tomatoes. We also know that while the seedsmen's catalogues still contain long lists of the old ones we used to grow, hardly any of them retain the same characteristics more than two or three years after their introduction. The more careful seedsmen will select them into an entirely different type, while the careless one will let them run back to some inferior ancestor. After we leave the little Pear, Plum and Cherry Tomatoes it seems almost impossible to get a fixed variety. I thought that I had the Dwarf Champion as completely fixed as any could be, but from a lot of carefully saved seed one-third made strong running vines with fruit exactly like the old French Tree Tomato, from which the Dwarf Champion, no doubt, defined its habit. Others seemed identical with Acme, and none that had the dwarf habit showed any fruit like the French Tree. The fruit was reproduced, but the habit lost, though some of the smooth fruits on the dwarf plants had the color of the original Tree form. The whole lot was a strange mixture. This tendency to continually sport in new forms, or rather to revert to old ones, is doubtless the reason for the diversity of opinion in regard to varieties. Year after year I have sown seeds of Ignotum, which has received high praise elsewhere, but I have never yet had any but inferior fruit from it. Careful selection will usually give us a majority of good fruit, but I have long since abandoned all idea of getting a perfectly fixed variety. I look for little further improvement in Tomatoes, except, perhaps, in making perfectly smooth sorts out of the big ones, like Ponderosa and Mikado. For market purposes this is hardly to be desired, since sorts like Stern, Matchless, Brandywine and Beauty are much better, and the extra large ones had better be left to the amateur.

The large grower cultivates mainly for the canning-houses, and they demand a smooth, medium-sized, bright red solid tomato. The big ones, with green ends and large hollows, make too much waste.

W. F. Massey.

Citrus trifoliata.—Your remarks on my note in regard to this plant are the first intimation I have had of its showing any degree of tenderness. The trees I planted eleven years ago in the uplands of northern Maryland, in a locality where the winter cold falls as sharply or more so at times than in New York City, have never shown any signs of tenderness, and fruit very abundantly. A gentleman in Ann Arbor, Michigan, who planted some at my suggestion, reported that they came through last winter. I do not know personally of any planting in New England, and am surprised to learn that they kill-back there. My plants in Maryland, on the terrible 1st of January, 1881, were exposed at noonday in a full sunshine to a temperature of four degrees below zero, with bare ground deeply frozen. They were little plants turned out of four-inch pots the previous spring, and had made long sappy shoots late in fall, as the plant is apt to do. I supposed that these late shoots would be killed, but, to my surprise, not one of them was hurt. I feel perfectly sure that, for all the Middle States and the south at least, this is the ideal hedge-plant.

Shrubs in Muck Holes.—Mr. Jack's notes on the European effort to grow Kalmias and Andromedas in water-tight tanks show how sensible gardeners often make sad imitations of nature's conditions. Any one who notices the growth of Kalmias and Azaleas on the northern slopes of our mountains could hardly fail to note that, while they thrive in cool and moist locations and a peaty soil, the localities are thoroughly drained by the rocky débris among which the roots wander, and moisture is due largely to the seepage of springs on the mountain-side above. No water-tight tank filled with peat meets these conditions. It reminds me of some of my early efforts to grow Rhododendrons in a limestone clay. I dug out deep beds and filled them with peat, and for a time the plants, in their imported balls of peat, bloomed, and I thought I had made a success. But the excavations in the clay, filled with the mellow peat, were only so many drainage-holes for the surrounding soil, and after three years of gradual starvation I found that the plants had not made a root outside of the original balls in which they came from Belgium, and every one could be lifted entire as though they had been in a pot, while the mass of peat in the bed was as sour as in its original swamp-bed. Some of these half-dead plants were removed and planted in the edge of a wood, on a steep rocky hill above the lime soil of the valley, and have since then grown with all the wild luxuriance of our native mountain plants. It is a bad plan to excavate beds for any plants in a compact clay, unless some arrangement is made for drainage. Such drain-holes in a compact clay filled with peaty soil might do for Arundos, Cannas and Caladiums, but never for the hair-like roots of our hard-wood forest shrubs.

Correspondence.

The Gypsy Moth and its "Extermination."

To the Editor of GARDEN AND FOREST:

Sir,—We have now had two seasons of legislative attack upon the Gypsy moth in Massachusetts, and can properly consider the desirability of its continuance and the best means of dealing with an insect whose destructiveness is conceded. Nearly \$100,000 have been spent—in the first year \$26,170.27—by a paid commission composed of men without special qualifications for their task, and who naturally went to work in a rather bungling manner, but succeeded in destroying, no doubt, a great many insects. When they were discharged it was supposed that the district over which the insect had spread from its original centre at Medford covered only about eight or nine towns, with an area of, say, fifty square miles, whereas in two or three months' time it was shown by the new unpaid commission (afterward the committee of the Board of Agriculture, but consisting in the two cases of the same persons, one of them a scientific man of high and deserved repute) that the moth had spread over twenty-one—now thirty—towns and cities, and an area at present estimated at about two hundred square miles.

In the second year, under the new control, \$68,616.60 have been spent, and the Board of Agriculture, in making its report, asks for a further appropriation of \$75,000 "to carry on the work according to the plans laid out [but nowhere stated] for 1892," and a resolution appropriating that amount for "continuing the work of exterminating the insect" has been introduced into the House. It is plain that no such sum should be allowed, and that whatever sum is appropriated should be directed toward preventing the spread and checking the ravages of the insect, and not toward its extermination.

This is not said in criticism of the work of the board the past season. It has worked under great disadvantages, and doubtless felt obliged under the "extermination" appropriation to leave untried no possible means of effecting its purpose. Men had to be trained to do the work, and few of them could have worked to their full efficiency until the close of the season, so that with the same force and the same expenditure vastly more could now be done than then. Nor, if we put aside the notion of extermination, can it be said that they were not successful. When three men in two days' time destroy over one hundred thousand caterpillars and chrysalids, and when more than three-quarters of a million of egg-clusters, representing from three to four hundred million possible caterpillars, are destroyed in six weeks by a force of less than two hundred persons, or over one hundred batches of eggs per day per person, we must believe that they have worked to good account. But one of the clearest proofs of their success is given in the fact that after the fall of the leaves, the men, now better experienced in the work and sharper-sighted, gathered

only about one-tenth as many egg-clusters as in the beginning of the year before the leaves were out. The work of the committee in fixing the boundaries of the infested district is also much to be praised.

But all this is not extermination, nor is it a great way toward it. It is an easy task to destroy a vast number of insects when they swarm. To wipe out the straggling and scattered remnant is an infinitely greater undertaking, nor could it be greater than with an insect which thrives on almost every green thing, and is spread over so wide a tract densely covered with vegetation. Not a half-million of dollars carefully spent would effect it. It must be remembered that the insect originated from a few individuals introduced into Medford; a few individuals left over from "extermination" would again introduce a reign of terror and frantic effort. What we now need is a patient and well-directed control over the increase and spread of the insect, and nothing more.

The report of the board assures us that the back of the offender is broken. There are now no large colonies. "Where in past seasons the trees bore neither leaves nor fruit, this year (1891) a good crop has been realized." The regions of their greatest abundance are well known and mapped; the position of every outlier is marked. Work for the future can be better and more economical because more intelligently directed. Work that was possibly justifiable when the insect swarmed, and when "extermination" was the fad, is so no longer. The cutting down and burning of brush sprayed with petroleum, similarly spraying and firing stone-walls, spraying indiscriminately with Paris green all foliage in a given district—work which the committee repeats is costly and very expensive—would be a reckless waste of effort and of money.

There are practically but two modes of attack on the insect: one while it is in the egg state, more than half the year, and when the leaves do not hide it; and the other for a few weeks only, while it is a roaming caterpillar, more or less concealed. The director of the field-work the past year, speaking of the former, says, "experience has shown that this is the most practical method of dealing with the moth." The details of the report bear out the assertion.

If, then, work is to be directed simply to keep the insect well in check and prevent its spreading, no such expenditure as was made last year is at all needed. A steady force of twenty, or possibly of ten trusty men skilled in the work, and under efficient direction, ought to suffice for two or three years. They could go systematically over the ground for eight months in the search for eggs, and for the remainder of the year on watch against outbreaks, and when such outbreaks occur the caterpillars could be captured and destroyed by the best devices, and the trees next to roadways could be specially guarded. No doubt we can learn by longer practice still better and more economical means of contesting the ground with the foe. It might be well to add a small bounty to boys for every ounce of eggs delivered, though they are now prohibited from aiding in this way, for fear that, in removing them from the trees, some eggs of the cluster may be left behind—a precaution bred of the "extermination" craze.

Cambridge, Mass.

S.

Aquatics at Farview, Staten Island.

To the Editor of GARDEN AND FOREST:

Sir,—The southern end of Staten Island has long been a favorite residence of New York families, and all the eligible locations outside of the Government reservations held for the harbor defenses are occupied for country-seats, generally handsome residences and extensive pleasure-grounds. The island at this part rises rapidly from the beach, with a succession of gently sloping eminences known as the Dongan Hills. Farview, the estate and summer home of Justice C. L. Benedict, of the United States District Court, bears an entirely appropriate name, for the handsome villa commands one of the most remarkable outlooks in the vicinity of New York city. At the south-west the eye ranges over Raritan Bay at its widest, with Sandy Hook in the dim middle distance, while to the left the noble entrance of New York harbor is in full view. The Narrows at the east are always full of the movement of the commerce of the port, and present a constantly changing picture, full of life, no sound of which reaches the observer. The view at the north is bounded by irregular hills, while at the west the ridge which makes the backbone of the island furnishes a quiet sylvan view in contrast to the others. Such a site seems to be an ideal one for a country retreat for a dweller in a large city, for here he can enjoy quiet surroundings, with the suggestion of activities in full view, and yet without disturbance.

The extensive grounds of Farview are mostly well-kept lawns. There are a few good trees on the place, though many have been thinned out for interfering with the outlook. Coniferous evergreens are used freely, with a good collection of the smaller sorts. Some beds of hardy perennials are gay in their season, as are the many tender plants. But the charm of the place to many would be the Lily-tanks, which, in the summer, under the supervision of your correspondent, Mr. Wm. Tricker, have become famous. Mr. Tricker will be remembered by many as the first man in this vicinity to grow large exhibition-blooms of Chrysanthemums and as a winner of first prizes for several years. Mr. Tricker, besides being superintendent of the estate, has become a trade grower of Chrysanthemums and aquatic plants. It was especially to see the latter in their winter quarters that I called a few days since.

The borders of the outside tanks were covered with littery manure and evergreen boughs to prevent the walls from being broken by the frost. The water was retained in one deep tank, while from another it was drawn off and the rhizomes deeply covered with leaves. Both methods are said to preserve the hardy *Nymphæas* successfully in this latitude. In the houses I found a very large and complete collection of *Nymphæas* in all stages, which were especially interesting, as their propagation in quantity is a comparative new industry, and in some respects is still somewhat tentative. Mr. Tricker seems to have succeeded admirably, having new houses fitted up gradually as experience suggested. Besides the half casks in available spaces, where proper temperature could be secured, used to store stock, the plant consists of shallow wooden tanks, zinc-lined, occupying the bench room of a low span-roofed house. These are heated with a one inch pipe led from the four-inch floor and carried back to the return. Mr. Tricker thinks this furnishes too much heat, especially when the main pipes are very warm. Seedlings are grown in flats and pots plunged in these tanks and shifted on as they develop. It is a simple matter to germinate seeds of *Nymphæas*, but the necessary warmth as quickly develops algæ, and the problem is to carry the seedlings through the weak stage without being suffocated by those minute organisms. The necessary trouble would scarcely commend itself to a small grower. Possibly the difficulty may be obviated by arranging for a flow of filtered water at proper temperature. Judging by the stock grown, the favorite *Nymphæas* seem to be *N. Zanzibarensis*, *N. Devoniensis*, *N. dentata*, *N. chromatella*, *N. alba candidissima*, *N. odorata rosea* and *N. speciosa*. Monsieur Martiac's newer kinds, *N. albida*, *N. sulphurea*, *N. rosea* and *N. exquisita*, are still very scarce, and hardly known to ordinary growers. *N. flava* has been discarded here, *N. Mexicana*, though very close to it, being much freer in flower. The beautiful seedling of Dr. Bahnsen's, described in GARDEN AND FOREST as *N. superba*, is being distributed from here as *N. Caroliniana*, and promises to be a vigorous plant.

Elizabeth, N. J.

J. N. G.

Hardy Broad-leaved Evergreens.

To the Editor of GARDEN AND FOREST:

Sir,—This place is nearly in the latitude of Philadelphia, but the ocean is only thirty miles away on the east. Tide-water in the Delaware River is about the same distance on the west, and the ocean about twice that distance on the south. Our soil is light and warm, and I have noticed that cold waves reported as coming across the country are quite apt to be headed off by a counter current from the ocean, and therefore fail to reach us. These conditions should be kept in mind in order to check or explain some statements I am about to make in response to Mrs. Dandridge's request for experience with half-hardy plants. *Magnolia foetida* does finely without protection. I have one which is now going through its third winter, and there are three standing singly and fully exposed in the lawn connected with Mr. Parry's nursery, about six miles north-east from Philadelphia, but on the New Jersey side of the Delaware. These were planted in 1887, and were then two to three feet high. I suppose they are now about fifteen feet high, and pictures of health and vigor, and one of them produced seven flowers last summer. The only injury they have received is from retaining so much snow as to break some of the branches, but they are at present full and symmetrical, and show no signs of ever having been injured in this way. I should feel safe to plant it anywhere in the southern half of New Jersey, and there are many places nearly as far north as Philadelphia where it will succeed in favorable positions. *Araucaria imbricata* has stood out here for twenty years, and has never been injured by cold except in one unusually severe winter, when a portion of the top was killed. It is now thriving again, although it grows

quite slowly. It is in very poor sandy soil, and has had little or no care. This tree may not be properly classed with broad-leaved trees, but it bears very little resemblance to ordinary coniferous evergreens, and in fact has about as much the appearance of a Cactus. It is always of a dark rich green, and a very interesting tree.

Lonicera fragrantissima is very nearly evergreen here, and I think would be so a little farther south; it is a very desirable plant, producing its very sweet-scented flowers all through the spring months, and often having both flowers and ripe berries in May. The Japanese Privet is yet full of leaves, and although it makes a very regular upright growth, which is rather stiff and formal, it is desirable in some positions. We have growing wild in the wet swamps near the Mullica River a vine which is greatly superior to the Bitter Sweet as an ornamental berry-plant. I allude to *Smilax Walteri*. It grows, so far as I have observed, invariably where the ground is fully saturated with water, and usually among dense thickets of Alder, *Andromeda*, *Azalea*, etc., and its slender stems attach themselves by tendrils to these shrubs, and produce in great profusion very compact small clusters of brilliant light scarlet berries about the size of those of *Ilex verticillata*, which remain on all winter. I have never seen this in cultivation, and it might not be hardy so far north if removed from the water. It would be almost impossible to dig the plants from the thickets where they occur, but seeds sown in pots or boxes at this season and placed under the greenhouse benches come up freely in spring. It is one of those plants which have been neglected quite too long, and most certainly would succeed wherever even a narrow strip of low marshy land lies along slow-running streams, if not on upland. It is not nearly as thorny as some other varieties of *Smilax*. It is not evergreen, but if it was desirable to plant an evergreen vine with it *Smilax laurifolia*, which also grows in similar situations, or a little nearer to the upland, would serve the purpose.

Hamonton, N. J.

William F. Bassett.

Recent Publications.

The Silva of North America, a Description of the Trees which grow naturally in North America, exclusive of Mexico, by Charles Sprague Sargent, illustrated with figures and analyses drawn from nature by Charles Edward Faxon, and engraved by Philibert and Eugène Picart. Volume III. *Anacardiaceæ—Leguminosæ*. Large 4to, pp. 141; 50 plates. Houghton, Mifflin & Co., Boston and New York.

The third volume of Professor Sargent's *Silva of North America*, which has recently appeared, is devoted to the illustration of the trees which belong to the families of *Anacardiaceæ* and *Leguminosæ*, and completes, we should imagine, a quarter of the whole work. So far as trees are concerned, North America is not rich in representatives of either of the families treated of in this volume, as compared with some other parts of the world, where, especially in the tropics and in Australia, arborescent *Leguminosæ* abound, while in the smaller and less-interesting family of the *Rhuses* are many exotic genera with arborescent representatives. Of the trees of this family which are included in our *silva*, none are especially valuable to man, although among the American *Sumachs* will be found some of the most ornamental of the smaller trees. This volume begins with a description of the American Smoke-tree (*Cotinus Americanus*), the genus *Cotinus* first established by Linnæus and afterward united with *Rhus* being here, contrary to the custom of most American authors, maintained principally, no doubt, on account of the remarkable growth of the pedicels of the sterile flowers, which lengthen after the flowering period, and turning bright-colored give the peculiar aspect to the plants of the genus which has made the Old World *Cotinus* so prized in gardens. The American Smoke-tree is one of the rarest of all our trees, growing only in two or three isolated situations from the mountains of northern Alabama to western Texas. The distribution of the genus is interesting and rather unusual; two species only are known; one of these, the Venetian *Sumach*, or Smoke-tree, is a common plant of southern Europe, ranging east through some parts of India to northern China, without, however, reaching Japan, while the second, barely distinguished from its Old World prototype, has only just succeeded in maintaining itself in the New World, from which it seems destined to disappear at no very distant day.

Of the true *Rhuses* five species are here considered to become North American trees, four belonging to the Atlantic, and one to the Pacific flora. *Rhus Metopium*, a handsome, although exceedingly poisonous, West Indian tree, inhabits the keys of southern Florida. Two *Sumachs*, *R. typhina* and *R. co-*

palina, are represented by beautiful figures, those of the former perhaps the most attractive in the volume; certainly none others better display the artist's patient labor or his artistic method in the arrangement of his material. More interesting, perhaps, than any of the *Sumachs* is the familiar Poison Dogwood of our northern swamps (*R. Vernix*), on account of its near relationship to the Japanese Lacquer-tree. Of the cultivation and uses of this tree in Japan, the most valuable of all the *Rhuses*, the reader will find most interesting information embraced in the copious notes upon several exotic species which the author has appended to his general description of the genus *Rhus*. Here, too, is an account of Chinese galls, excrescences found on the leaves of *R. semialata*, a beautiful tree now well known in our gardens; of the Vegetable Wax of Japan, the product principally of *R. succadadenea*, and of the European *R. coriarea*, which furnishes the larger part of the *sumach* of commerce, and of its cultivation. *R. integrifolia*, the only California representative of the genus described, is usually a low shrub, covering with almost impenetrable thickets vast wind-swept areas exposed to the ocean in the southern part of the state, and occasionally, especially south of the territory of the United States, a tree with a short thick trunk.

It is an interesting fact that no arborescent representative of the family of *Leguminosæ* grows naturally in California beyond the desert region of the south, although the family, in many shrubs and in almost numberless herbs, furnishes one of the most marked features of the California flora. Of the genus *Dalea*, a New World group of a hundred species, there is one representative in *The Silva* (*Dalea spinosa*), a small contorted bushy tree of the Colorado desert, which, perhaps, a less conscientious author would have dropped entirely in a work on trees, as it is usually a shrub, and, except for the small amount of soft, light and usually half-rotten wood its stems might furnish to a traveler lost in the desert, of no value whatever. Frémont discovered it in one of his transcontinental journeys, but it was Thurber, years afterward, who made its characters known, and to this excellent and learned man, whose death was announced in these columns a year or two ago, the author here pays a fitting tribute.

A few small *Mimosæ*, one of the great divisions of *Leguminosæ*, cross our southern borders from Mexico, east of the Rocky Mountains, and are sometimes, especially in the valley of the lower Rio Grande, rather conspicuous features of vegetation. They are representatives of *Acacia*, *Leucæna*, *Pithecolobium* and *Prosopis*; among them is the well-known *Acacia Farnesiana*, one of the most widely distributed of all trees, and an inhabitant of Australia as well as of many parts of tropical America. This is the *Cassie* of the French, who cultivate it in all the territory bordering the Mediterranean for the perfume which is extracted from the flowers. But the most important of all the *Mimosa* group of North America is the Mesquite (*Prosopis juliflora*), the most valuable of all the North American arborescent *Leguminosæ*, and one of the most valuable of trees in view of the fact that it has the power, through the immense development of its roots, which sometimes penetrate fifty or sixty feet into the ground in search of water, to grow in regions so arid that no other tree can survive there. The Mesquite furnishes the only fuel produced in an enormous region, and the best fodder, for the sweet pulp which surrounds the seeds enclosed in long pods is devoured by all herbivorous animals, and furnishes a valuable article of food to Mexicans and Indians.

In this volume, too, will be found accounts of many trees now familiar in the gardens of the United States and in those of Europe—the *Virgilea*, the Kentucky Coffee-tree, the Three-thorned *Acacia* and its relative, the Water Locust, the Red-buds, and the Locusts—and of a few that are not as well known to the general reader, such as *Olneya*, a beautiful inhabitant of the deserts of Arizona and Sonora; *Ichthyomethia*, the fish-poisoning tree of the Caribs and an inhabitant of southern Florida, as well as of the Antilles; the two Texas *Sophoras*, handsome small trees of a genus known in our gardens in its Asiatic representative, *Sophora Japonica*, and the *Cercidiums* or Green-barked *Acacias*, curious trees of the territory of the Mexican boundary, which they enliven with their bright green branches, destitute of leaves during a large part of the year, and their brilliant yellow flowers.

But a mere enumeration of the trees contained in this volume can give but a very faint idea of the character and extent of the information which it contains. This is not confined to American trees alone, for under the description of the genera included in the work will be found, in the form of notes, a vast amount of important and curious information relating to the principal trees of each from other parts of the world—the

fruit of years of study and careful preparation, much observation and many long journeys. And, in turning over these handsome pages, it is hard to realize sometimes how much information is contained in a few lines of one of the short notes, or in what convenient form it has been conveyed to the reader.

Notes.

In an article in the *New York Sun* on Photography, by Mr. George Iles, it is stated that Mr. Olmsted, the designer of the exhibition-grounds at Chicago, receives photographs of the grounds once a week, which show how his plans are taking form. In such a report there can be nothing forgotten or glossed over.

The Worcester County, Massachusetts, Horticultural Society will celebrate on the 3d of March the fiftieth anniversary of its incorporation. An address, historical and narrative, will be delivered in the hall of the society in Worcester in the afternoon by its President, the Hon. Henry L. Parker, and in the evening a banquet will take place.

The Torrey Botanical Club, of this city, announces that the prize of fifteen dollars offered last spring for the best set of plants collected within one hundred miles of New York has been awarded to Miss Anna Murray Vail, whom our readers will remember as the author of several interesting articles published during the past year in GARDEN AND FOREST.

The new Rose, Hugh, which originated with Mr. F. S. Moore, of Chatham, New Jersey, is highly spoken of in the *American Florist*. It is a sport from Catherine Mermet, and the flower has that peculiarly deep shade of pink which is occasionally found in the very best flowers of that variety. It is large, full, well formed, and is said to be a strong grower.

The Genesee Valley Forestry Association, of which Mr. A. S. Hamilton, of Rochester, is President, and Wheelock Rider, of the same city, is Secretary, seems to be an alert and vigorous young body. Its Executive Committee has recently issued an address to the people of western New York calling attention to the desirability of the preservation and renewal of forests, and giving reasons why systematic forest-culture should begin at once in that region.

The Japanese consider it especially difficult to arrange Chrysanthemums, and seven faults are noted which must carefully be guarded against in disposing of large blossoms of this plant. A blossom must not present its back in a composition, nor yet turn its full face to view; the different flowers must not have stems of the same length; three must not be arranged in a triangular form, nor may any number be placed in a regular step-like way; the flowers should not be hidden by leaves, nor should a large open blossom be put near the base of the composition; and, finally, the artist must not fall into the sin of color-sandwiching, or placing a blossom of one color between two others of another tint.

The early commencement of the publication of a *Prospectus Floræ Africae* is announced by Th. Durand, of Brussels, and H. Schinz, of Zurich, in which they propose to bring together and condense the immense mass of information relating to African plants which is now so scattered through different publications as to be unavailable to the ordinary student. The work when completed will embrace some 20,000 species and 80,000 synonyms, including the new species collected by different travelers in Senegal, Angola, at Zanzibar and on the upper Congo. The price of the work, which will be published in six volumes, is 120 francs (about \$20) to subscribers, who can communicate directly with either of the authors.

In a late bulletin of the Michigan Agricultural College a report is made as to the comparative value of a hundred and twenty-eight varieties of Strawberries tested there. Each variety has been grown both in matted rows and in hills, and from the table it is shown that almost uniformly the yield of fruit under the hill system is much greater than that from the matted-row system. Nor is this the only advantage of planting in hills, because the increase does not come so much from a greater number of fruits as it does from their greater size and beauty. The following varieties are named in the order of their maturing as a select list for home use throughout the season: Alpha, Haverland, Parker Earle, Belmont, Parry, Mount Vernon and Gandy. This year Parker Earle yielded a greater weight of fruit than any other variety, and it did the same last year.

Chief-Justice Hagarty, of the Province of Ontario, administrator for Lieutenant-Governor Campbell, in the speech with

which he opened the session of the Legislative Assembly, at Toronto, last week, stated that a commission had been appointed to report upon the desirability of establishing a forest-reservation and park in a portion of the Nipissing District south of the River Mattawa. The proposed reservation is situated on the height of land in which the rivers Amable du Fond, Pettewawa, Bonnechère, Madawaska and Muskoka have their sources. It is to be hoped that the report of this commission, which is to include a discussion of the proper methods of maintaining and managing the reservation, will be such as to meet the favor of the Legislative Assembly. In this country we already have some reservations, and are endeavoring to secure more of them, but as yet we have no scheme for maintaining them as a forest should be maintained, if it is to serve its highest purpose.

Professor Bailey, in a late bulletin from the Cornell Experiment Station, gives an account of some trials made there with *Stachys Sieboldii*, the comparatively new vegetable which has also been introduced under the names of *S. affinis*, *S. tuberosa* and as *Crosnes du Japon*. In cultivation here it is a small perennial plant with the aspect of Peppermint, and there is some doubt among botanists as to whether it is really distinct from the common wild *S. palustris*, which grows over a large part of North America. Its value as a food-plant lies in the white tubers, which are thickened underground stems, like potatoes. Although they are small, they are produced in such abundance that the plant yields heavily. After eating the tubers prepared in several ways, Professor Bailey pronounces the plant, in his view, the most important addition to our list of secondary vegetables which has been made in several years. The tubers can be prepared in a great variety of ways—fried, roasted, baked, pickled, preserved, stewed in cream and made into fancy dishes, or they may be eaten raw. They may be dug as wanted during the winter, and, ordinarily, enough of the roots will be left in the ground to ensure a supply in the following year. Much of the value of the tubers depends on their crispness, and they must, therefore, be kept in earth or in moist shavings, for they will shrivel in a few hours if exposed to the air. The plant lacks a good common name, and Professor Bailey suggests *Chorogi*, by which name it is known in Japan.

Mr. J. W. Wibbe writes to the *Bulletin of the Torrey Botanical Club* that he had long doubted the assertions of several acquaintances who declared that the Musk-plant (*Mimulus moschatus*), which is so old a favorite for indoor cultivation, grew wild in Saratoga County, in this state, but that last July he saw it himself. Driving along the Kayaderoseras to the mouth of a famous trout-stream called Moorehouse Brook No. 1, about a mile north-west of Middle Grove village, he says "The very first things I met here after crossing the bridge were whole patches of the *Mimulus*, hanging over the banks of the brook-let with their frosty foliage perfuming the whole atmosphere. Following the course of the water the plant was found wherever a clear space was left for the sun to shine upon the loamy soil. About one mile up the creek, in full view of the foot-hills of the Adirondacks, the plant has its headquarters in a springy swamp, growing in all directions in the midst of the water, often two feet high. A trapper informed me of having known the plant here always and nowhere else in the neighborhood. How this far-western plant came there I am not able to tell, but it is there and in great abundance." The editor of the *Bulletin* adds that the *Mimulus* was also found a few years ago growing in a boggy swamp about two miles east of Locust Valley, in Queens County, on Long Island, "perfectly at home, and scattered over a considerable area," and that a specimen from this locality is preserved in the herbarium of Columbia College.

The Tree as a Schoolmaster.

TO those who study it with care and sympathy, the tree is always teaching lessons which help to enlarge and elevate the mind. From it can be derived instructions of profound significance, of high philosophy, of practical suggestion, as one considers its meaning, its history and its economic value in the world.

First of all it teaches man to reserve judgment by showing that the insignificance of a germ is no criterion of the magnitude of its product, that slowness of development is not an index of the scope of growth, and proves to him that the most far-reaching results can be attained by very simple means. A barrel of acorns may be the nucleus of a forest that shall cherish streams to fertilize a desert, a handful of Cedar-cones may avert an avalanche, while a bushel of Pine-seed may prevent the depopulation of a great section of country by mountain torrents.

Studying little by little the influence of the forest, we come to understand the intimate relation between man and nature—that relation which is a struggle of rival forces, in which the silent, mighty mother inevitably wins the battle. If at the first glance man seems her ruthless adversary, the tormentor of the earth, the wrecker of woods, the destroyer of beauty, the boastful pigmy who would assault a colossus, we soon come to learn that in wronging her he but evokes a doom as sure and terrible as his assault has been reckless and violent.

Like the fierce blow of Thor's hammer upon the face of the giant Skrymir, mistaken by that mighty one for the fall of a leaf, the puny strokes of man, though they may scar, cannot destroy, and when the Earth giant awakes from slumber it is to confound the weak assailant with a sense of the impotence of his fancied strength. Then one hears once more the mocking laughter of the Jötuns at the baffled mortal, and hears the echo of their scornful cry, "Better come no more to Jötunheim."

Of the tree man in due course learns the law of the survival of the fittest, since in the end the forest must prevail

if he but cease his vigilance. He learns it in the struggle of the monarch of the woods to reach above its fellows in the hungry roots which dwarf less vigorous growths in its broad arms, which push aside its weaker companions; in the crown of leaves which overshadow its lesser rivals; in the powerful shaft that thrusts its lance skyward above the surrounding conifers; in every effort of the tree-king to assert its right to supremacy above the others.

Then comes the study of the tree's prodigality of production, the enormous care for the protection of the species, the thousands of seeds yielded for one that germinates; that endless provision for the future forest; that patient shelter of the youthful sapling which shall gain nourishment from the decay of parent leaf and stem.

Slow, beautiful and sure is the yearly development of the young tree. Without haste and without rest it stretches upward, adapting itself to its environment, as man to his. But, unlike him, it will not readily be weaned from its natural surroundings. The Willow clings to the stream, the Chestnut to the stony hill-side, the Pine and Fir to the mountain-top; and in the useful ends they serve, each in its proper habitat, we learn another lesson of simple duty and faithfulness to our daily lot. Does the Spruce-tree quarrel with its sea-smitten crag? the Maple with its forest-seclusion? the Cedar with its lonely swamp? Does the Oak seek to divest itself of its twining Ivy? the Birch sigh to escape from its marriage with the Pine. Not so; and here again they preach a needed sermon to the restless race that frets away its uneasy life beneath their shade.

Not even when the fall approaches does your tree put on a wintry countenance. Rather does it array itself in gold and purple for its last pageant, strewing the earth with a splendid carpet, which enwraps the new fallen seed or nut, and thus ensures to it a future growth. Even when the last leaf clings to the stem, the tree is a fair sight to those who truly love it and can rejoice in the exquisite outline presented by its denuded branches, the soft interlacing of its twigs, the fine curves of limb and bough, the rosy brown shadow of its tips closely interwoven in a thread-like web against the pale blue of a winter sky.

Even so a fine character meets disaster and loss, braced for the blast. What matters it that adornments are shorn away if the revealed life is full of vigorous beauty, of unconquered energy, of powerful promise, shall not the future of the brave though shivering tree give courage to the man shorn of his wealth or joy to put forth buds of hope for a spring that is to come? Thus does the tree as a schoolmaster lead man from the great preliminary lessons of eternal law and progress, of development and growth, down to the more homely and needed schooling in patience, endurance and calm confidence in a hopeful future.

Then, when its economic uses are to be considered, a wide field opens to the tree-student, as he learns how great a part it plays in every enterprise of man. To it he owes his dwelling and his boat, his oar and his weapon, often his clothing, and his meat and drink; it has modified his character, determined his history, and been a staple of his commerce with other lands. Far-reaching has been its influence upon the race from prehistoric days until the time when the wooden walls of England became the bulwark of that liberty of which our independence is the outcome. Thus the story of the tree leads to the history of the race, which it has so strongly influenced, and opens out the whole human horizon to its pupil. Hence he who makes a companion of trees and seriously seeks to learn the secret of their importance, finds his own mind and knowledge constantly expanding with the effort to master this ever-widening topic.

As the subject grows he himself grows, his silent but wise instructor conducting him step by step to higher and wider outlooks; to a more comprehensive grasp of information; to a keener understanding of humanity; to a deeper reverence for nature; while filling him with unending surprise at the educational resources of that school-

master which has opened to him the door to the whole world of knowledge.

IN our issue for January 20th appeared extracts from an address before the Forestry Convention, in Washington, by Mr. J. D. W. French, in which was advocated the employment of the army to protect the forests of the national domain, and especially the forest-reservations recently created by the President. In connection with this Mr. French suggested a Professorship of Forestry at West Point, and a school in one of the western reservations to teach the soldiers practical forestry. There are few things more depressing than the dull routine of camp-life on the plains, and it is small wonder that so many enlisted men desert from the army. There is a strong movement in favor of increasing the facilities for giving instruction to our soldiers in time of peace, and no doubt a better class of men would enter the service and would remain in it if some plan of wholesome mental discipline was devised. Mr. French's suggestion, that the men should have some instruction in woodcraft, is an admirable one, and it would furnish them with a kind of schooling which does not necessitate confinement over books.

We have lately received, through the kindness of Mr. Fernow, a letter which was sent to the Forestry Division by Mr. Abbot Kinney, of California, in which he suggests that these forest-reservations should be at once utilized as schools. It is his opinion that, while we cannot follow the admirable French system of organization, we might devise something which combines the features of the systems used in France and in the Indian Empire; since a military or half-military plan would give a basis for discipline, would permit the temporary use of the army as guardians, and would make the service more attractive. On this last point Mr. Kinney makes the following very interesting statements:

"Lieutenant Wood, in command of the Yosemite Guard, is very enthusiastic over the effects of the patrol work on his men and horses. He says that the work makes better soldiers and better men of his command, and that men and animals are infinitely better prepared for any real military work than they could be by any garrison duty. He speaks also of the greatly improved moral tone of the men."

It has always been our judgment that the best thing which could happen to the forests on the national domain, after withdrawing them from sale and entry until proper legislation could be had for their management, would be to place them at once in the charge of the army. From another view of the situation, it would seem that the carrying out of this project would also be the best thing which could happen to the army.

The Elms of the St. Lawrence Valley.

GEOGRAPHICALLY, a considerable portion of northern New York and Vermont belongs with Canada; at least it is in the valley of the St. Lawrence. Indeed, the basin of the St. Lawrence includes the entire Champlain Valley, ascending southward almost to the Massachusetts line; while in what is known locally as the "Y" of the Green Mountains (a tract enclosed on the south by the main range and an eastern branch of it which diverges toward the north-east and reaches almost to the Connecticut River), all the streams flow northward, and become, by the way of Lake Memphremagog and the St. Francis, tributaries of the same river, so that a strictly geographical boundary along the southern rim of the St. Lawrence basin would award two-thirds of Vermont to the Dominion. It is noteworthy that, farther east, the northern boundary of New Hampshire and Maine follows the watershed.

It is well known that the geological characters of our portion of the great valley (and, in consequence, its soil) are very different from the rest of New England. Limestones, slates and marbles replace the granitic and gneissoid rocks, and although the marks of the ice age, with its erratic boulders, are everywhere present, the soil itself very closely resembles that of the Ohio River below Cincinnati. As the coral ledges of the Falls of the Ohio, at Louisville, indicate that the ocean, or

a great arm of it, once covered all of the region of the lower Ohio, so the discovery of an entire and perfect skeleton of a white whale near the banks of Lake Champlain, in excavating for the track of the Rutland and Burlington Railroad, indicates that New England and the maritime provinces once constituted a great island, separated from the continent by a strait occupying the Champlain and Hudson valleys.

Soil is a strong factor in determining the arboreal characters of a country, and although there is all the difference due to latitude between the trees of the Hudson and Connecticut valleys and those of their northward extension through the Champlain Valley and the territory embraced by the Green Mountain Y, yet aside from this influence the forest-vegetation continues to be similar, and in marked contrast with that of the granitic soils to the east and south of it, not so much, however, in species (although there is a difference here) as in the vigor and freedom of growth. This is seen in the general aspect of the forests; but since these have been so extensively removed it shows itself more noticeably in the single trees. All down the Champlain Valley to the Canadian frontier, and thence to the bank of the St. Lawrence, we see no diminution in the size and vigorous spread of the Elms, which make so marked a feature of the river-landscapes below. The Elm is one of our "iron-clad" trees, and it develops itself as freely here, on the highlands around Memphremagog, as in lower New England. The picturesque variety of form which the Elm assumes is even more conspicuous, I think, in this region than elsewhere; and often, in accompanying tourist friends in a sail down the lake, I have listened with pleasure to their exclamations at the varied beauty of form and outline against the sky of the long procession of Elms to be seen on the edge of the high land rising from the eastern shore. This is the first step, or bench, referred to by me in a previous article, as a conspicuous feature of the country at this point. At the west shore of Memphremagog the Green Mountain region ends, and, after rising by successive terraces, the land spreads away to the north-east toward the St. Lawrence and upper St. John valleys—one of the finest sections of farming land, and certainly much the largest, in all New England and eastern Canada.

Not so much care has been taken here to preserve the fine large Elms of the original forest as southward, and the comparatively recent settlement of the country has not allowed planted trees time to reach a great size. But there is one of the old settlers remaining, that stands on the main street of the village of Derby Line, and is worth going far to see. I have never been able to get its dimensions, but it is evidently a tree of the original forest, quite straight and branchless for half its height, which can hardly be less than eighty feet, with a diameter, at a guess, that must be five or six feet, with very little tapering in the first half of its length. The great usefulness of Elm timber to the early settlers, for the construction of carts, implements, etc., has caused the older growth to be closely culled of all the straighter trunks, and such trees are comparatively rare. But no tree is more perfectly at home here, and none grows more rapidly from the seed. Although our people are not yet much given to setting out road-side trees, yet the readiness with which the Elm springs up in the shelter of the road-side fences is such that it is the most common natural growth in such positions; and now that our fence laws allow the removal of these fences, the appearance, save for an irregularity of distance, has much the effect of a planted avenue on all of our older highways. Trees that have in this way grown up in my own fences within twenty-five years are eight and ten inches in diameter. The peculiarity of the Elm to assume a great variety of forms is especially seen in these seedling growths, where they have not been crowded. The vase, or wine-glass, the pen or feather, the weeping, the columnar, the spreading and various other more or less eccentric developments are seen abundantly; in fact, there is no tree that presents so many varying aspects as the Elm, and for that reason it may be used alone for avenues with far less monotony of effect than any other tree.

While our White Elms have such a variety of forms, I have not noticed here any examples of the Cork Elm (*Ulmus racemosa*), which is comparatively abundant in the Champlain valley and westward; but the Slippery Elm (*U. fulva*) is quite plenty, and though it never becomes a large tree it grows more rapidly even than the White Elm while young, and will thrive well in a drier soil. Trees of this species always attract the notice of observing persons by their darker, thicker and rougher foliage, and in the spring by their large, dark brown buds. It is quite as hardy against climate as the White Elm, and the foliage is less attacked by insects.

Newport, Vt.

T. H. Hoskins.

Notes of a Summer Journey in Europe.—VIII.

AN excursion to the famous nurseries of L. Späth, at Rixdorf, a few miles out of Berlin, is expected of every one who visits the German capital with any interest in horticulture, or more particularly in arboriculture. Visitors are numerous, and are always welcomed and shown the resources of the place, which covers so much ground that only a superficial inspection of it can be made in a day. My own visit here was much too short to enable me to obtain a proper conception of its resources. It is one of the largest nurseries in Germany, if not in Europe, covering about 600 acres devoted to the propagation of forest, ornamental and fruit trees and shrubs, while a great business is also done in herbaceous and bulbous plants. Lilies-of-the-valley are raised in enormous quantities for forcing purposes. A walk among the large blocks of vigorous plants of Späth's Golden-leaved Dogwood and other variegated plants, purple and variegated-leaved Maples, and thousands and tens of thousands of other plants, either in their natural state or with some abnormal peculiarity, gives one something of the feeling that this is a great plant factory instead of an ordinary nursery. Plants are turned out in such quantities that one may fancy they are made by machinery instead of brought up by hand in the old-fashioned way. The propagation of variations of trees and shrubs seems to be a great feature here, and perhaps more is made of slight differences than is necessary for the advancement and welfare of horticulture. This, however, is a common fault among nurserymen, and in some cases the distribution of such plants may be a necessary stepping-stone to the really distinct things which are occasionally brought out. Too often, also, the variations propagated are the merest monstrosities or the result of disease. The enumeration of so many forms swells the lists enormously, so that it is hardly surprising when we are told that Herr Späth's nurseries contain over 6,000 species and varieties of trees and shrubs, besides nearly 1,000 varieties of Roses and 700 or 800 of fruits. It is said that nearly three million ornamental and fruit trees are always ready for the yearly sales. Grafting is much resorted to as a means of increasing the stock of some things, and tens of thousands of conifers are treated in this way.

As it is impossible to show all visitors over such a large establishment, a small collection or arboretum of the most striking plants has been formed near the principal offices, so that much time may be saved by those who only desire to see specimen plants of kinds they wish to procure. This collection is arranged in groups according to genera, and although there is not room for the trees to develop into large specimens, a fair idea of their habit and general appearance may be obtained. They are all neatly and distinctly labeled with permanent porcelain labels.

Very different from the great commercial nursery or plant factory of Herr Späth are the private nursery and garden and the beautiful country home of Baron von St. Paul at Fischbach, at the foot of the Giant Mountains, in Prussian Silesia, where two days were delightfully spent. Baron St. Paul is another enthusiast in horticulture and arboriculture, never resting or being satisfied with his collection so long as he hears of something which may prove better than anything he already possesses. His garden is famous throughout all the surrounding country, and the road-sides and little gardens in the neighborhood give abundant proof of his influence by the unusual plants or flowers which are seen. The situation is a most beautiful one, in a country mostly divided into large estates, yet like one great park, stretching away in meadows, fields of thriving crops and areas of woodland and forest. Behind the house is the great rock known as the "Falkenstein," while before it lies a series of gradually rising hills terminating in the "Schneekoppe," the highest point in the range, which separates Prussian Silesia from Bohemia.

Fischbach is situated about 1,200 feet above the sea, and in winter the temperature sometimes falls as low as ten degrees below zero of Fahrenheit, while the summers are probably cooler than the average summer of New England away from the mountains. As the conditions and climate more nearly corresponded to what I have nearly always been accustomed, and more than any place I had yet visited, I was particularly interested in the variety and condition of the trees and shrubs grown here. Baron St. Paul's grounds are filled with the best hardy trees, shrubs and other plants procurable, and their whole arrangement shows remarkable taste and appreciation of natural beauty as well as an intimate knowledge of the character of the plants he has to deal with. By joining with Max Leichtlin and others in sending collectors to new or little-known botanical territory, some interesting and valuable rarities have been secured, so that, besides the ligneous plants, we

find here Anemones, Irises, Primulas, etc., as yet little known in the horticultural world. These are often planted in quantity in grass or meadow, or by the side of water if such situation suits them best.

One of the first familiar objects seen on entering the grounds was large masses of our wild *Rosa lucida*, which, although so late in the season (August 9th), was still blossoming well. Although it grows luxuriantly and flowers abundantly, it does not fruit very freely here. *R. Carolina* was just coming into good bloom. Both the purple and white flowering varieties of *R. rugosa* are much and well used, and it is deservedly considered one of the finest of all hardy natural shrubs. I was shown a hybrid between this Rose and *Gloire de Dijon*, which has semi-double flowers of a beautiful blush color. It was interesting to find here a vigorous plant, five or six feet high by as much across, of the single flowered Japanese *Viburnum tomentosum*, recently figured in GARDEN AND FOREST (vol. iv., pp. 594, 595). It was still bearing a few stray blooms. The "Snowball" form, known as *V. plicatum*, now frequently seen in American gardens, is considered rather rare in Germany. Among numerous familiar New England plants I noted the little Bear Oak (*Quercus ilicifolia*) in full fruit, and *Magnolia glauca* in a thriving condition and still flowering. The *Cucumber-tree* (*M. acuminata*) is hardy enough, but some difficulty is experienced with the *Umbrella Magnolia* (*M. tripetala*), as it is liable to be more or less killed every winter. The same trouble is often experienced in New England, and it is often only by repeated trials and much patience that decent specimens may be obtained. At the north it does best where the soil is not too rich or very moist. The European Walnut is barely more hardy than it generally proves in the vicinity of Boston, still it lives in an unsatisfactory way. The Chestnut grows fairly well, but does not fully mature its fruit in this locality.

Many of our American conifers flourish here, among them *Chamaecyparis Lawsoniana* and *C. Nutkaensis*, and *Abies nobilis*. The form of *Tsuga Pattoniana*, known in gardens as *T. Hookeriana*, is much prized here and elsewhere in Germany for the fine blue color of its foliage. While Jeffrey's Pine refuses to grow well, our common White Pine reaches perfect development.

The European Larch here is sometimes seriously injured, and even killed, by case-bearing larvæ of a little moth (*Coleophora laricella*), which eats out all of the interior of the leaves, leaving only the dry, white and shriveled epidermis; but it is a curious fact that the Japanese Larch (*L. leptolepis*) has not yet been affected by the pest. The insect has been introduced and known in Massachusetts for a number of years, and its ravages are sometimes quite noticeable. At the Arnold Arboretum this pest, probably imported with Larches, and the destructive Larch saw-fly (*Nematus Erichsonii*) have been observed and noted for several seasons, and although both have been very abundant I have never known them to affect the Japanese Larch. While it is hardly probable that this immunity can be lasting, it is interesting to know that these insects should have so far avoided this tree. My host informed me that for killing insects on Orchids and other plants he found plunging them into hot water heated to forty degrees Centigrade very effective, and it apparently caused no injury to the plants.

It was interesting to find American varieties of fruits undergoing trial here, and to see our northern Fameuse, or Snow Apple, and others flourishing. Few good peaches ripen in the open air in this part of Germany, but some of our early American varieties, such as Early Alexander and Early Beatrice, do mature. Although fairly good, these American peaches are not considered nearly so richly flavored as the later-ripening French varieties.

The road-sides in this region are often finely shaded by handsome specimens of the native Linden (*Tilia ulmifolia*) and the Ash (*Fraxinus excelsior*). The European Mountain Ash, or Rowan-tree, is also planted along road-sides, but it does not grow so large as it does in the mountains. What is called an edible fruited form of this tree has been found in the mountains of Bohemia, on the other side of the Giant Mountains, and it is now propagated and planted to a considerable extent.

The forests of the mountains here are chiefly composed of Spruce and Fir, and the planting of young woods of these trees is chiefly done in August and September. Large reserves are maintained as hunting-parks, and on these the forests are never entirely cut off, but are thinned out gradually or have small sections cleared in the interior, so that the park-like and woodland effect of the landscape is not marred. Between the Giant Mountains and Görlitz there is some fine farming country,

where steam-plows, steam-threshers, etc., are sometimes employed; but in the low land between Görlitz and Berlin large tracts of the country are sandy and infertile, and here Scotch Pines have been planted on soil where little else but Lichens seem to be able to get a foothold. Some stretches are covered with Heath (principally *Calluna vulgaris*), and the young Pine-trees are set in the midst of it. The planting of these Pines is chiefly done in the spring; they grow slowly on such poor soil, and do not get to be of very large size.

Arnold Arboretum.

J. G. Jack.

The Swan's-neck Orchids.

THERE is a very remarkable American genus of plants known as *Cycnoches*, or Swan's-neck Orchids, which occupies a kind of sporadic or transitory position in our collections, though its species possess a quaint kind of beauty which is peculiarly their own, and none are more interesting to the naturalist. Like *Catasetum*, it has the peculiar habit of producing two very different kinds of flowers on the same plant, and these have a trick of appearing in the most unexpected and extraordinary fashion. Sometimes a plant whose behavior has been of the most orthodox character will suddenly produce flowers of a totally novel kind, in some respects almost as different as are those of *Cattleya* and *Odontoglossum* from each other. Occasionally the two kinds will be borne in different racemes on opposite sides of the same pseudo-bulb, and more rarely they will even appear intermixed on the same raceme. For many years the significance of these phenomena remained a complete mystery, and the early history of the genus is a mass of confusion. For some time I have been trying to unravel the tangled history of the genus, and only quite recently have I succeeded in getting to the bottom of the matter so far as existing material is concerned. And now I am anxious to obtain such further materials as will enable me to complete a monograph of this most interesting group.

The genus was originally described by Dr. Lindley, from a single flower; and the generic name is in allusion to the long slender curved column, which very closely resembles the neck of a swan, though this character is only exhibited by one of the two kinds of flowers.

No sooner had this original species become established in cultivation than it began to exhibit those peculiar propensities for which the genus soon became famous, as will be seen from the following extract from the *Botanical Register* for August, 1837: "In August, 1835," writes Lindley, in a note under t. 1,947a, "Mr. Willmer, of Oldfield, near Birmingham, sent me a specimen of a *Cycnoches*, which had broad petals, a short column, hooded and dilated at the apex, and a broad roundish lip, gibbous at the base, and with its stalk much shorter than the column. It was, however, destitute of scent, while *Cycnoches Loddigesii* has, as is well known, a delicious odour of vanilla. I had no doubt of its being a distinct species, and called it *C. cucullatum*. But in the autumn of 1836, in the garden of the Horticultural Society, a plant of *Cycnoches* produced from the opposite sides of the same stem two racemes; those of the one raceme were the well-known fragrant flowers of *Cycnoches Loddigesii*, and of the other the scentless flowers of the new *C. cucullatum*."

A few years later a still more remarkable case appeared, as is recorded by Bateman at t. 40 of his splendid work, *The Orchidaceæ of Mexico and Guatemala*, in 1843: "Strange things," he writes, "and no less strange than true, have already been recorded of Orchidaceous plants, but the case which is represented in the accompanying plate casts into the shade all former frolics of this Protean tribe. The facts are briefly as follows: Among Mr. Skinner's earliest Guatemala collections, attention was particularly directed to the specimens of a plant which to the habit of a *Cycnoches* joined the long, pendulous stems of a *Gongora*, and for the possession of which, in a living state, no small anxiety was entertained. Some plants were speedily transmitted by Mr. Skinner, but these on flowering proved to be merely the old *C. ventricosum*. A mistake was of course suspected, and Mr. Skinner, being again applied to, sent over a fresh supply of plants, for the authenticity of which he vouched; but these were scarcely settled in the stove when flowers of *C. ventricosum* were again produced. Mr. Skinner being importuned for the third time, and being then on the point of returning to this country, determined to take one of the plants under his special protection during the voyage, which, flowering on the passage, seemed to preclude the possibility of further confusion or disappointment. The specimens produced at sea were exhibited, and the plant itself placed in the stove at Knypersley, where it commenced growing with the utmost vigour. The season of flowering soon arrived, but brought with it a recurrence of the former scene

of astonishment and vexation, for the blossoms, instead of those of the coveted novelty, were not distinguishable from the old *C. ventricosum*. These were still hanging to the stem, when the inexplicable plant sent forth a spike of a totally different character, and which was, in fact, precisely similar to the specimens gathered in Guatemala, and to those produced on the voyage.

No solution, however, of these mysterious phenomena was arrived at, except that they were what gardeners call "sports," and Lindley indulged in some rather wild speculations about the species being masquerading under false faces. But we now know that the species are sexually dimorphic, and that the phenomena observed were simply the production of the two kinds of flowers on the same individual. And this has furnished the clue to a very curious error committed by the artist who drew Bateman's plate. Instead of showing the female flowers of *C. Egertonianum* he has introduced the males of *C. ventricosum*, probably because the former were too much withered to be restored, and moreover the two were so much alike that they were actually thought identical. It is highly curious that the female of one species should be so much more like the male of another species than like its own, yet such is the case, and the plate in question exhibits the peculiar phenomenon of the males of different species growing on the same pseudo-bulb. Probably the artist acted on instructions, for the female of *C. Egertonianum* had been thrice mistaken for *C. ventricosum*. The female of the latter species was then unknown.

This great diversity between the sexes, however, does not extend to all the species of the genus, for in the case of *C. chlorochilon*, perhaps the best-known species in gardens at the present time, the differences between the male and female flowers are confined to the sexual organs—that is to the ovary and column—as the sepals, petals and lip are quite identical in each. This fact is very curious. Although the species has been known for upward of half a century, and has been largely cultivated, the female flowers do not appear to have been observed before the summer of 1891, when they appeared both with M. Lehaie, in Belgium, and with Messrs. F. Sander & Co., in England. It is just conceivable that they may have appeared before and not been noticed, owing to their similarity to the males, though no existing figure of the plant and no dried specimen that I have come across shows them. However, their occurrence was a matter of considerable interest, for it led to the clearing up of the confusion into which the history of the genus had fallen. It is now evident that the genus contains two distinct sections, one in which the sepals, petals and lip are practically identical in the two sexes, and the other in which they are quite dissimilar. In both, however, they are borne in separate flowers. In the females the ovary is normally developed and very stout, and the column short and stout, with a pair of fleshy, triangular wings, and the stigma perfect, but without the anther. In the males, on the contrary, the ovary is reduced to the pedicel of the flower and much thinner, while the column is long and slender, without the wings or stigma, but with the anther and pollinia normally developed. Thus the term swan's-neck only applies to the column of the male flower.

The section *Eucycnoches* (which contains the original species of the genus), in which the two sexes are nearly alike, comprises the following six species:

1. *C. chlorochilon*. Flowers very large, perianth similar and equal in the two sexes, bright yellowish green, the lip yellowish white, with a prominent dark green crest near its base. Racemes few-flowered. Native of Guiana and Venezuela.
2. *C. ventricosum*. Male racemes longer, and with more numerous and smaller flowers than the preceding, and the lip cream-white. Female flowers fewer, rather larger and more fleshy than the males. Native of Guatemala. This is said to have been seen to sport into *C. Egertonianum*, an error which arose from the females of that species having been confounded with the males of the present one.
3. *C. Lehmanni*. An Ecuadorean species, closely allied to *C. ventricosum*. The male flowers are yellow with a green callus; the females are unknown. It is not in cultivation, and I only know it by description.
4. *C. Loddigesii*. Male racemes about 4–6-flowered; sepals and petals brownish green, the former with darker spots; lip whitish, spotted with blood-red near the base. Female flowers fewer, rather larger, and more fleshy. Native of Surinam.
5. *C. Haagei*. Male racemes long, pendulous, and bearing numerous medium-sized flowers, much like those of the following species. Females unknown. I only know the species by description. Native of Brazil.
6. *C. versicolor*. Near the preceding, but apparently distinct. The sepals and petals of the male are of a very peculiar

dull, velvety olive-green, and the lip yellowish white with a few reddish brown spots. Native of Brazil.

The section *Heteranthœ*, so-called because of the great diversity between the flowers of the two sexes, comprises about nine known species as follows:

7. *C. Egertonium*. Female flowers dull olive-green, in shape

radiating clavate fleshy appendages. The segments are purple-brown, or blotched with that color on a green ground. Native of South Mexico and Central America. This is said to sport into *C. ventricosum*, an error which arose from the females of *C. Egertonium* having been wrongly identified with that species.

Fig. 15.—*Symplocos cratægoides*.—See page 90.

like those of the previous section, solitary or borne in pairs on a short suberect raceme. Males much smaller, more membranous, and borne in long, pendulous racemes. The lip is reduced to a small, round disk, surrounded by a number of

8. *C. Dianœ*. A Central American species, closely allied to the preceding, of which the males only are known. They are crimson spotted with brown, and a white lip. It is only known from dried specimens.

9. *C. Rossianum*. Closely allied to the two preceding. Female flowers dark green. Males blotched with purple-brown on a green ground, and borne in very lax racemes. Native country not known, but probably Central America. Only known in cultivation.

10. *C. glanduliferum*. Male flowers light green, spotted with brown, lip white. Females unknown. Native of Mexico.

11. *C. peruvianum*. A Peruvian species, closely resembling the last. Male flowers only known.

12. *C. Warscewiczii*. Flowers of both sexes wholly green; in other respects resembling the preceding species of this section. Native of Central America.

13. *C. aureum*. A handsome Central American species. The male flowers are large, bright yellow, and borne in pendulous racemes. The females are unknown. It appears to have been lost to cultivation.

14. *C. maculatum*. Male flowers large and borne in long, dense racemes, green spotted with brown. Females unknown. Native of Venezuela.

15. *C. pentadactylon*. Male flowers larger than in any of the preceding, and borne in short, few-flowered racemes; yellowish green, barred and blotched with dark brown. Teeth of the lip reduced to five. Females a third larger than the males and far more fleshy, with similar colors, but the spots are chiefly concentrated toward the base of the segments. Native of Brazil.

New or Little-known Plants.

Symplocos cratægoides.

SO much interest has been awakened among the lovers of hardy shrubs by the notes that have appeared from time to time in these columns on the merits of this plant as an ornament of the garden and the shrubbery, that, at the request of some of our readers, we have had prepared for their benefit the portrait which appears on page 89 of this issue, from one of the plants in the Arnold Arboretum. There is little to be added to what has already been said of this plant. It is a hardy tree-like shrub, which will doubtless grow in time to a height of ten or twelve feet, and perhaps even to a greater size. The flowers, which resemble those of the Hawthorn, although they are rather smaller than the flowers of the Hawthorns of the northern states and of Europe, are produced in the greatest profusion during the month of May. In the autumn the branches are covered with clusters of small fruit of the most beautiful and brilliant ultramarine blue. The color of the fruit is the most remarkable characteristic of this plant, and it is this that makes it such a valuable garden-plant.

Symplocos cratægoides is distributed from Japan to northern India, and, as is natural in the case of a plant that inhabits an area of such diversified climates, it assumes very different forms of foliage and of habit, and botanists have at different times bestowed upon it a number of different names. It is to Mr. Thomas Hogg, one of the earliest American travelers in Japan, and one of the most successful introducers of Japanese plants, that our gardens owe this beautiful shrub, which deserves all the attention it has received during the last two or three years, and which must rank among the very best hardy plants in cultivation. The plant was sent to the Arboretum several years ago by the Messrs. Parsons, of Flushing, Long Island.

Clematis paniculata.

THIS plant has already been figured in GARDEN AND FOREST (vol. iii., p. 621), and attention has often been invited to its singular value as an ornamental climber. It is surprising that such a handsome plant, which was introduced into Europe nearly a hundred years ago, should have remained so long practically unknown. The happy thought of Mr. Orpet to graft it on our common wild species, *C. Virginica*, and afterward upon *C. stans*, showed how easily it could be propagated, so that everybody now has an opportunity of testing its merits. The plant from which the illustration on page 91 was made is trained on the western side of the residence of Walter Hunnewell, Esq.,

Wellesley, Massachusetts. It was raised from seed, and is now four years old, and has bloomed for two years. Last season it covered about a hundred square feet, but because the space it could occupy was limited it had been pruned back severely, or it would have otherwise spread over twice as large an area. The photograph of which this illustration is a reproduction was taken on the 12th of September, and the plant in the latitude of Boston begins to bloom about the 20th of August, when most other species of *Clematis* are covered with seed.

Mr. T. D. Hatfield, who sends us the photograph, states that the stems of the plant are left on the trellis, and are quite unprotected. Some of his plants have a north-western exposure, but they have endured the winters of four years without the slightest injury, the wood keeping sound and breaking to the top. Under such treatment the lower parts of the stems sometimes are bare, so that it is advisable to cut them back to encourage the growth of new wood.

Prunus hortulana.

THE hardest puzzle in American pomology is the classification and nomenclature of the native cultivated Plums. Something over 150 varieties are known to cultivation, and these are commonly referred, loosely, to two species, *Prunus Americana* and *P. angustifolia* (*P. Chicasa*). But the varieties represent at least two other species, and perhaps even more. One of these species, which appears to have escaped botanical recognition, includes a large class of Plums represented by Golden Beauty, Cumberland, Garfield, Sucker State, Honey Drop, probably Wild Goose, and others. The species appears to grow wild over a large part of our interior region from Kentucky and Illinois to Texas. It is readily distinguished from our other species by its long ovate-lanceolate and acuminate leaves, which have finely and evenly serrated edges, by long and glandular petioles, and by glandular and more or less pubescent calyx-lobes. The fruits are red or yellow with thin skins and more or less translucent flesh, a very thin bloom, and a juicy sweet flavor. The fruits are later than the Chickasaws, to which these plums have been mostly referred for many years. For this species, which I shall describe more fully on another occasion, I propose the name *Prunus hortulana*.

The Adulteration of Copper Mixtures.

AT the late meeting of the Western New York Horticultural Society, Dr. Van Slyke, chemist of the Experiment Station at Geneva, read an interesting paper giving an analysis of some of the substances used in spraying plants. The substances analyzed were copper sulphate, commonly called blue vitriol; copper carbonate and copperdine, a special preparation, said to be a mixture of copper carbonate and ammonium carbonate, in the proportions recommended by the Department of Agriculture. Without going through the details of the analysis, we give the summary of the conclusions reached, which are of practical importance, since the copper mixtures are so largely employed against the fungous diseases of cultivated plants.

Copper sulphate, in the form of large crystals, may be regarded as being fairly pure, but when in the form of powder it is always safe to test its purity. Copper carbonate, on account of its rather high price, and also on account of its powdered condition, is probably quite liable to adulteration, and should always be tested. Copperdine, in the dry form, costs twice as much as it ought to, but contains the official proportion of copper. Copperdine, in liquid form, costs three or four times as much as it ought to, and, as regards the proportions in which its use is recommended, it is only one-half or one-third as strong as it should be.

While the help of a chemist is needed to tell how much copper a substance contains, the following suggestions will enable

any one to test copper sulphate and copper carbonate as well as Paris green in regard to their purity:

Copper sulphate, if pure, should dissolve completely in water, making a clear solution, free from sediment or suspended matter.

Copper carbonate should dissolve completely in nitric acid, commonly called aqua fortis. If it does not dissolve completely, it is impure and probably adulterated. Copper carbonate, if pure, should dissolve completely, or very nearly so, in a considerable quantity of strong ammonia-water. Both tests should be used. Of course, copper carbonate could be adulterated by using powdered copper sulphate, but this could easily be detected, since copper sulphate easily dissolves in water, while copper carbonate does not.

Paris green should, if pure, dissolve completely in strong ammonia-water, used in liberal quantity.

Such simple tests as the foregoing may be applied by any one, and they will serve as a fairly reliable guide regarding the purity of the compounds mentioned. When adulterants are added they have been found by common experience to exist in the form of some finely powdered white substance, as

in appearance there may be seen the dark fruiting spots of the fungus, where the spores are borne in large numbers. This form of damping-off is particularly contagious, on account of the rapidity with which the spores germinate. By actual test cases of inoculation, fully developed spore-bearing spots have been produced upon healthy Carnation-stems in three days when these stems were kept moist, as are the portions of cuttings below and at the surface of the sand. Gardeners have frequently observed that some stock is much worse than others with this cutting-trouble, which, in large part, can be accounted for on the ground that the fungus is not uniformly distributed in mature plants. Stock free from it will be apt to remain free, but diseased stock, in like manner, is quite sure to decay in the sand.

The failure of Rose-cuttings to grow may be due, of course, to various causes, but the one that has been most frequently met with of late is fungus belonging to the genus *Gloeosporium*. This fungus forms minute pimples in the bark of the diseased wood, followed by an exudation of a gelatinous spore-mass from each pustule that is, at first, rose-tinted, becoming almost brick-colored. The branches of many Rose-plants in

Fig. 16.—*Clematis paniculata*.—See page 90.

barium sulphate, for example, which is insoluble in water, alkalis or acids.

Fruit-growers who have to use large quantities of copper compounds should, for the sake of economy, buy the separate ingredients and do their own mixing. Persons who have occasion to use only small amounts of spraying mixtures may find it advantageous to purchase prepared compounds ready for use, if they can be sure that the preparation is reliable in strength and not extravagantly high in price.

Fungus Troubles in the Cutting Beds.

DURING the past few weeks particular attention has been paid to some diseases in the cutting beds. Among those found dead or badly decayed are cuttings of Carnation, Rose, Clematis, Passion Flower and Chrysanthemum. In the Carnations, for example, the cuttings begin to decay at the surface of the sand, the outer leaves soon rot at the base and fall to the ground. This is due to an anthracnose of the genus *Colletotrichum*, and long before the cutting has become ruined

a feeble condition have been examined microscopically, and this fungus has been detected. While we have not found it naturally upon the foliage there was no difficulty in inoculating leaves with the *Gloeosporium*, by placing them in contact with diseased stems in a moist chamber. Rose-wood that is only slightly diseased with this anthracnose when made into cuttings would probably fail, because the new conditions would be particularly favorable for the growth of the fungus. As in the case of the Carnations, the obvious precaution is to use healthy wood.

Many Chrysanthemum-cuttings have failed, and an examination of a considerable number of these leads to the identification of at least two fungi, either one of which is sufficient to account for the trouble. During the past year Chrysanthemums have suffered a good deal from the presence of a fungus of the genus *Septoria*, which caused the severe blighting of the foliage in some instances, almost defoliating the plants. This same *Septoria* is present in abundance in the cuttings that have damped off. Other plants, obtained from other greenhouses, and appearing in the same plight, have a *Phyllostiata*

as the destroying fungus. The differences between these need not concern the practical grower.

The wholesale loss of cuttings of Abutilons in some propagating-houses is also to be traced to diseased wood and to a fungus that is similar to, if not identical with, the *Colletotrichum* of the Carnation. Experiments were made in growing cuttings of the Abutilons of several varieties and inoculating them with the fungus. In a few cases the transfer was successfully made, and there seems but little doubt that the dying of the cuttings of even such woody plants as the Abutilon may be due to germs which pass from one plant to another.

Nasturtiums, in the same way, are frequently attacked by a *Colletotrichum*, and when cuttings are made of plants thus diseased they damp off and because of the succulent nature of the cuttings, they almost entirely disappear. Clematis, Jessamine and Passiflora cuttings behave much like those of the Abutilons, and are attacked by the same or by a similar anthracnose. The inference from it all is to be careful and use healthy wood.

Byron D. Halsted.

The Vegetable Garden.

A GREAT many new Beets are continually offered, but, for family use, my own opinion is that the old Extra Early Bassano is as good as any. Some object to its light color; but this is only a fancy, for in quality it is vastly superior to the dark Egyptian. Its big top makes it objectionable to the market-gardener, but as I am writing mainly for amateur gardeners, I would say use the Bassano and Eclipse for early sowing, and sow a few seed a little earlier than you consider safe. Once fairly above the ground, they will stand some frost; but if caught just as they are coming up, they are easily killed. Here we sow the first in February and early March—a month, at least, later for latitude of New York.

Some gardeners sow Salsify and Parsnips very early because of their hardy nature, but I have found that this is an error. The early sowings get into a stunted condition about midsummer, and later on begin to grow again. In this latitude Salsify makes its best crop sown in July, while at the north seeds sown in June will make better roots than those sown earlier. The Sandwich Island Salsify is so much better than the old sort that we use it altogether. If the Cabbage-plants in cold frames are properly hardened off by gradual exposure to the air, they may in this section be set out the middle of February, and in New York and New Jersey in March. This refers to the plants raised under glass in January and February. The fall-sown plants are out long ago here.

While spring-sown Spinach does not amount to much, it can very well be allowed to occupy the land intended for Snap Beans later on. The Beans can be sown between the rows of Spinach, and by the time they need work the Spinach will be over.

Onions sown now in a cold frame and transplanted later on to the open air, we find to make a much heavier crop than if sown and thinned out where they are to grow. The cold frames can now be used also to good advantage in growing early Radishes and Early Horn Carrots. Here, Radish-seed can be sown on a sunny border, and covered with straw when a cold wave threatens.

Raleigh, N. C.

W. F. Massey.

Anemone Japonica.

IN order to have good specimens of this handsome plant for blooming in early autumn it is necessary that they should be potted and placed in a cool house early in March. By so doing nearly a month is gained in the blooming season. They will commence to grow almost at once, and by the middle of May, after a little necessary hardening, can be plunged out-of-doors. This should not be done until all danger of frost is passed, as I have found from experience that the foliage is very easily scorched. Foliage thus disfigured remains on the plants the whole of the season, and spoils their appearance.

We use good rich loam, which is packed quite firmly, leaving more than the ordinary space for water. All the soil is shaken away and the small roots cut off. Nothing but a clump of twelve to fifteen crowns is left, and these are kept about the centre of the pot. If for no other reason than the removal of the young roots, I should repot them every year, as every piece of root is so prolific in the production of young plants that if left unpotted a second year about all we should have would be a forest of suckers or young plants, completely impoverishing the soil.

Abundance of water is needed to produce bold, handsome specimens, and no plant I know, except, perhaps, the Chrysan-

themum, sooner shows the want of it. When the flower-stems appear in July I begin to give manure-water, and continue it weekly until the flowers begin to open. I have often wondered why florists do not grow this plant. All admit its value for cut flowers. It is easy to grow, and no pest or disease, as far as I know, troubles it. All that would be necessary is a cold frame, with a little litter at the sides and mats and shutters for covering. They could be planted in ordinary loam about six inches apart, and one foot from the glass. All the attention required during winter would be occasional airings on bright days. After the 1st of March they should be opened regularly and the sun heat stored, whenever possible, by closing early in the afternoon until they are well started into growth. Gradually, and whenever the weather permits it, the sashes may be removed, and when danger of frost is over altogether, plenty of water and good feeding should be given until the flower-buds begin to open, and then a slight structure ought to be erected, so that a light waterproof covering of oiled cotton cloth could be stretched over merely to prevent rain spoiling the flowers.

There are several varieties, but two only can be recommended for trade or private purposes. These are the white variety, known as Alba, and sometimes called Honorine Joubert, and the pink one, known as Hybrida, which resembles the white variety in everything except the color of flowers.

Wellesley, Mass.

T. D. H.

Solandra grandiflora.

ALTHOUGH introduced more than a hundred years ago, this plant is still rare; so rare, indeed, that I have never seen it grown anywhere outside of botanical gardens. This is not due to any lack of good qualities on the part of the plant, nor to any real difficulty about its cultivation, but rather to the erroneous impressions that it is difficult to manage.

The genus *Solandra* differs considerably in general appearance and some important characters from the typical genus of the Solanaceæ. It was founded by Swartz in honor of Dr. Solander, and *S. grandiflora* is undoubtedly the best of the four or five species. It is a semi-scandent shrub of free growth and handsome appearance. The bright green shining leaves are deciduous, oblong, tapering both ways, at the base to a short petiole. The large funnel-like flowers, about seven inches in length by some five inches in width, are usually borne singly at the extremity of the young branches, and they remain upon the plant from four to six days after full development, the corolla being still perfect when it drops. The calyx is green, and when the flowers first expand the corolla is of a very pale green color, almost white in the locality of the lobes, changing gradually to a beautiful deep buff tint. It is not uncommon for as many as three flower-buds to appear on the extremity of a single shoot, but it is quite exceptional for more than two of them to survive the bud-stage.

A plant of this species flowers freely every winter in the Palm-house of the Harvard Botanic Garden, and at that time it is to the casual visitor a never-failing source of such wonder and admiration as is excited by a first glimpse of the *Victoria regia* in bloom. This specimen is grown in a pot of rather poor loamy soil, and the roots are never molested except to receive a slight top-dressing of similar material every autumn. Some of the roots have escaped from the bottom of the pot and seem to revel in the sandy gravel of the bench. The branches are trained close to the glass, where they enjoy full exposure to sunshine all the year round, and the night temperature of the house seldom exceeds sixty degrees Fahrenheit in winter. Little or no water is given the plant from the fall of the leaf onward until growth commences again in early autumn, from which time the supply is unstinted, necessitating ample drainage. *S. grandifolia* inhabits rocky situations in Jamaica; and cuttings of the half-matured wood root readily in sandy soil with the aid of a little bottom-heat.

Cambridge, Mass.

M. Barker.

The Kaffir Lily, botanically known as *Schizostylis coccinea*, is a beautiful plant of the Iris family, and the only one of its genus known in gardens. It is said to occur on the shores of rivers in Kaffirland, South Africa, whence it was introduced in 1863 by the Messrs. Backhouse, of York, England. The erect stems proceed from spreading roots, best described as half bulb and half rhizome, and are about two feet in height. They are furnished with long, sheathing, bright green, sword-shaped leaves, which lessen in size and number as the length of the stem increases, and terminate in a spicate, *Gladiolus*-like inflorescence. The narrow tube of the flower is greenish and about an inch in length, the regular, spreading, six-lobed limb two and a half inches in diameter, and of bright crimson-scar-

let color. On plants that have made good growth the flowers are produced with great freedom during the winter months, and they are excellent for cutting at that season, and last well in water. The Kaffir Lily may be grown in the open garden during the summer in a somewhat moist situation and rich soil and wintered in a sunny cold frame. But unless it is grown simply to supply cut flowers much of its usefulness as a decorative plant is lost by confining it to a frame, and therefore it is better if potted when taken up in autumn and placed in a cool greenhouse, where it should have plenty of moisture and occasional applications of weak liquid manure to the roots. Under such conditions it will help materially to brighten the house through the greater part of the season, besides being handy for cutting if necessary. It is easily propagated by dividing the roots late in spring. When cultivated in a greenhouse, and the flowers allowed to fade upon the plant, the seeds ripen freely in our climate, and these, when obtainable, afford the best means of increasing the stock. They should be sown in slight heat under glass, and picked off and transplanted in the open garden when about six inches high, taking care that the change of temperature is not too abrupt. In this way nice plants may be obtained in one year from the time the seeds are sown.

Cambridge, Mass.

M. Barker.

Correspondence.

In the Shore Towns of Massachusetts.—VII.

To the Editor of GARDEN AND FOREST :

Sir,—While my principal errand in the shore towns was to find out what open spaces for public resort have already been provided, I also tried to learn as much as possible of the industries and resources of the people, of their thought and public spirit, of the local history, and whatever might tend to promote the objects of the Trustees of Public Reservations. I found everywhere recent changes in the ownership of land and a movement of people of means from the cities and the interior of the country to the shore regions of the state. I found leagues and leagues together of the shore-line all private holdings, without a rood of space in these long reaches to which the public has a right to go. I walked across the domain of one man who owns about six miles of shore-line. I found a great population inland hedged away from the beach, and all conditions pointing to a time, not remote, when nobody can walk by the ocean in Massachusetts without payment of a fee, as we formerly had to pay for a glimpse of Niagara. I could see that the movement for open spaces for public resort has vital relations to civilization, and has been instituted in response to a pressing need. I note some of the impressions which were oftenest repeated and most distinct.

1. Except in a few instances, the public holdings in these towns have not been measured, and their area is unknown. It would be well to have them accurately surveyed, the bounds marked and their area made a matter of public and authoritative record.

2. In a large proportion of the shore towns the public holdings have diminished in extent. Not only have all the old common lands, town pastures, woodlands and extensive shore holdings been parceled out to private possession, but the towns have permitted serious encroachments upon the smaller public holdings which were intended by the founders to be permanent. It is often evident that the first settlers had a pretty clear idea of the value of open spaces for public use in towns and villages, and they showed much foresight and public spirit in providing for them. But in later times these public holdings became the object of perpetual assault and invasion, and an astonishing amount of energy and ingenuity has been employed in the effort to appropriate public property to private use and possession. It often seems that the same labor in any legitimate industry might have brought prosperity to men who always remained poor, but they appear to have attributed their poverty to the failure of their attempts to seize the last small remnants of the public holdings of their towns. Those who have wished to despoil and appropriate the property of the town have, however, usually found their opportunity and incentive in the indifference of the community regarding public rights and duties, and invaders of the public holdings have gained title by undisturbed occupancy. The man who has wrongfully seized and kept the largest portion of the town lands is often regarded with admiration. "He was too long-headed for the town; he beat 'em at last."

3. In a large proportion of the shore towns there are no open spaces of any kind for public resort. Some inconvenience is already felt on this account, especially in the matter of places

for picnics and out-of-door assemblies of the country people.

4. Wherever the summer people have bought land on the sea-shore they show a disposition to exercise the right of exclusive domain, and to repel as trespassers all who wish to enter upon their grounds, and the people of the region are thus excluded from places where rights of public resort and passage have been exercised for generations. Even where the ancient public rights are clearly legal they are being generally relinquished.

5. The most important feature in the present condition and prospects of the shore towns is the change in the population which is going on everywhere, and the resulting transfer of the title to the land to new holders. There is a general movement of moneyed people from the cities and towns of the whole country east of the Mississippi River to the shore towns of this state. Individuals, companies and associations are buying land everywhere along the shore. Besides what is done openly, some citizen in each town acts as agent for principals who prefer not to be known. Some of these say they are buying for New York men, but capitalists in various interior cities are investing here. It is largely a movement of people able to have fine places for either summer occupancy or permanent residence by the sea. The extent of some of these new holdings on the shore is remarkable and ominous.

6. Except at Salisbury Beach, Plum Island and a few other places there is not yet much foresight of the need of sites for summer cottages to be leased to people of moderate means. Most of the real-estate men prefer to sell their land outright. They do not want the trouble of leasing it or of collecting rents. The hope of a great advance in the price of their land is more attractive to them than a permanent revenue from property requiring supervision and management. Yet even money needs care and oversight, unless it is handed over to the endowment societies or invested in some of the securities with which New England people have made acquaintance during the last few years. At some points on the shore money invested in cottages or sites rented to persons of small income would probably yield a good return.

7. Many farmers and residents in the shore towns have recently sold their land at very low prices, being rather surprised at any actual offer. When it sells at a great advance soon afterward, they feel that "the times are out of joint." When the native farmers sell their land, they ought to have fairly good prices for it. It is not likely that many of them will ever own land again.

8. Many of these men will be obliged to find new occupations, in order to make a living. The industries of the shore towns will be greatly changed by this movement into them of so many people, who seek only residence and recreation. Population of this character does not invite or support manufactures, but distinctly repels them. The old industries—fishing, whaling and ship-building—are nearly extinct, and much depression, anxiety and hardship result from the failure of the accustomed means of obtaining a livelihood. Some young men may find employment as coachmen, gardeners and common laborers for the summer residents, but foreigners from the cities are more likely to fill these places, and such communities do not offer employment to many laborers of any class except cooks and house-servants.

9. It is time to inquire what resources or opportunities will remain for the native people of the shore towns. There is one resource which has received comparatively little attention of late—the soil. The soil of most of the shore towns of Massachusetts appears to me much better than the popular estimate of it. It has greater capabilities than are yet recognized. This is especially true of the Cape Cod country. The soil there is better than that of southern New Jersey, and I have seen many Massachusetts men in Dakota, Montana and Idaho trying, in great privation, to make a living in regions much more forlorn and hopeless than any part of the shore country of the old Bay State. The productive power of the soil should be tested with crops for modern markets. It is not yet known what can be most profitably grown. Asparagus has been tried in Eastham and Orleans with encouraging results, and Turnips grown in other towns are said to distance all competition. The Cranberry industry is still expanding, and fruit-growing and market-gardening can probably be extended almost without limit and yield a good profit on the labor of the owners of the land. I think these towns might yet support a great population by a highly developed agriculture and horticulture, and that the owners of the land might wisely keep it and cultivate it. This would tend to delay the complete absorption and appropriation of the shore regions by summer residents from the cities, and would render the transition to new conditions less sudden

and abrupt than it is likely to be without this modifying effect, and such a postponement of the coming change is in every way desirable. If the farmers and land-owners of the shore towns can adapt themselves to the new conditions of life and make a good living out of their land, they would better hold on to it and stay where they are. But the army of summer incursionists will win in time, and will ultimately "occupy the land," as few American farmers have foresight enough to hold out against the offer of "a good price."

10. For any considerable improvement or development of the resources of these towns two things are indispensable—first, a readier acceptance of the necessity of downright hard work; and, second, a greater flexibility of mind and disposition on the part of many of the native inhabitants, enabling them to recognize the changing conditions of the time, and to take advantage of the opportunities which these changes present.

11. Although this movement and incursion of a new population is going on all around them, many of the native inhabitants are not aware of it. They know that two or three farms near them have been sold and have heard that a land company has bought a stretch of shore in the next town, but they do not put these things together or see their connection with a general movement. They have not observed that there is any movement or tendency in any direction, except that "times have been getting worse for some years now." They "rail at fortune in good set terms," and would rather rail than work. They lament the decay of the old good times, when their town had a fleet of several hundred sail and every man on Cape Cod was the captain of a ship, and they have no perception of the chances which the present time offers to resolute and capable men, and they thus sometimes neglect and reject opportunities of great value.

12. Some of the native people have a feeling of impatience regarding the changed conditions around them. They are depressed and snappish, and so make unfavorable impressions on strangers who are looking for land, or studying the country with a view to a choice of regions for investment. They do not think of the possible effect of civility or its opposite upon their own interests and affairs. One man, who found that he had been rude at the wrong time, remarked, in his astonishment, "I didn't suppose he was lookin' for land. I could a' sold him just the piece he wanted."

13. A wholesome competition in hotel-keeping would be a great benefit to some of the towns. There are some excellent houses which attract summer visitors, and give to all strangers favorable impressions of the country. Others reminded me of the mining-camp lodging-houses in the Rocky Mountain and Coast-range regions, and these hotels exert a potent influence in keeping people away from their neighborhood. I saw a New York man treated very uncivilly by the clerk and the company of hangers-on in the office of one of these houses. As we walked to the railway station next morning he remarked: "Some men are naturally civil; they are born that way; and a man with any sense learns to be civil because business requires it; but some infernal fools won't be civil even when they could make money by it." In another place I was talking with a town officer by the road-side, early in the morning, when some Boston people came along. They had passed the night at the hotel, and, finding it intolerable, had started out to try to find breakfast somewhere else. The ladies of the party were homesick, and wished they could take a train for Boston at once without waiting for anything to eat. The men joked the resident about his town and the hotel. He laughed, but made a gesture of vexation as he replied: "Yes, it's an old story. Everybody complains. Those who go there never want to see the place again. It would pay the town to buy the house and shut it up."

14. All the pleasant and comfortable sites along the seashore of Massachusetts are likely to be taken up, either by summer dwellers or permanent residents, before any general attention is given to the interests involved. The movement toward the shore has only fairly begun, and it is certain to increase with the density of the population of our country and the growth of wealth. Even now along vast reaches of the coast there is no area outside of the narrow highway to which the public has a right to resort to enjoy the sight or air of the sea. These conditions will be intensified, and the people of the state will be excluded from all interesting and attractive portions of the shore. These are abnormal and undesirable conditions, unfavorable to civilization, and all possible wisdom and foresight should be employed in the effort to secure adequate open spaces for public resort at different places along the coast.

15. Two questions constantly present themselves to one observing present conditions and tendencies in the shore towns.

a. Should there not be a broad public road or highway, or strip of public land, along the whole length of the sea-shore of the state? It need not always follow the water's edge, perhaps, but could be carried inland above the worst marshes.

b. Would it not be well to consider the question of limiting the length of the shore-line or ocean front of private holdings? The extent of the shore-line of the state is impassably limited, while the population of the country is certain to increase to an extent which is now almost unimaginable. Is it consistent with the public welfare that a few persons should have absolute possession and control of unlimited areas of the shore? What are the actual benefits which a man derives from the exclusive ownership and occupancy of four or five miles of sea-shore? What are the reasons which justify such a monopoly? The problem of title to the shore, and of the use and enjoyment of it by the people of the state, will in time be a vital and important public question here.

16. The subject of adequate playgrounds is forcing itself upon public attention in some of the shore towns, where the right of peaceable assembly out-of-doors is denied to boys, and they have no right to meet anywhere in the open air for athletic exercises, amusement or self-improvement. Every village and neighborhood should have out-of-door places of resort for the happy play and education of the children and youth of the region.

17. Some methods of acquiring public reservations are already provided by law in Massachusetts. There is, I believe, no general law under which towns may acquire land for the establishment of a system of water-supply. The towns which have done this have acted under separate special acts. But there is an act which enables water boards of towns to condemn land to protect the purity of their water-supply.

18. Chapter 157 of the laws of 1885 enables village improvement associations to improve public grounds or open spaces in any of the streets, highways or townways which the town may designate as not needed for public travel. They may grade, drain or curb such spaces, may set out shade or ornamental trees, lay out flower-plats, erect fences or railings, and otherwise improve such spaces, subject to the authority of the Selectmen or Road Commissioners. Approved April 13, 1885.

19. The Public Domain Act, approved May 25, 1882, authorizes a public domain loan and the taking of land by any town or city for the preservation, reproduction and culture of forest-trees, and for the sake of the wood and timber thereon, or for the preservation of the water-supply of such town or city. The title of all lands taken under this act shall vest in the commonwealth, and shall be held in perpetuity for the benefit of the town or city in which such land is situated. I think no action has ever been taken under the provisions of this law, and it is not likely that it will ever be carried into effect in practice.

20. Under the Park Act, approved April 13, 1882, towns and cities may take land within their limits for parks by vote of two-thirds of the legal voters present and voting in a legal town meeting called for the purpose, or in a city by the vote of two-thirds of each branch of the Council. The act authorizes bonds for a public park loan. Land beyond their own limits cannot be reached by towns or cities under this act. A number of towns have taken action under its provisions.

21. In Chapter 109 of the Laws of 1882 county commissioners are required, on request of ten or more freeholders, to ascertain the correct location of a public landing if it is doubtful or not readily known, to erect necessary bounds, and to make record of their proceedings, as in the case of highways.

22. The act to incorporate the Trustees of Public Reservations, approved April 21, 1891, confers powers which are practically almost unlimited within the scope of the objects for which the board was created. The corporation is authorized to acquire and hold by grant, devise, purchase or otherwise real estate, such as it may deem worthy of preservation for the enjoyment of the public, to the value of a million dollars, and another million of real and personal property to pay for taking care of the first million's worth, and to support or promote the objects of the corporation. The board can apply and use its funds in any way or manner adapted to support or promote these objects. No doubt the limitation as to amount could be extended if necessary, so that the board could receive and hold all that may be offered to it. It was understood at the time of its passage that this act would meet a want already existing, that some persons had property which they wished to transfer to such a corporation to be held for public uses, and that such gifts would be offered at once. The immediate consummation of such purposes would be a useful advertisement of the objects of the board.

23. The newspapers have been most prompt and cordial in their recognition of the undertaking, and their aid has been so intelligent and efficient that the popular knowledge of the enterprise is much more extensive and substantial than we could have expected to produce in so short a time. There is, however, no reason to expect that the objects of the movement can be attained without considerable direct effort to promote and support them. Means will be required for the systematic propagation and diffusion of ideas until the people of the state in general regard the enterprise seriously, and recognize its relations to civilization and the public welfare. If the movement is to be adequately successful much repetition will be necessary in the educational work required to produce a distinct and fruitful impression on the public mind.

24. Most people are so busy that but a limited amount of mental alertness or energy remains available for the objects of this movement. There is always much vague talk about progress, or the capacity for it, but no analysis of the subject has been seriously attempted in this country. I suppose the most that can be said by thoughtful men regarding it is that a narrow zone of improbability runs through the life of the best races. It is broader at some times than others, but it is never very wide. How far it extends, and what capabilities it includes, can be ascertained only by strenuous and intelligently directed effort to occupy and utilize it fully. Few efforts to influence public opinion are adequately directed, and the methods employed for this purpose are usually haphazard and unscientific.

25. I think the trustees should have a library and collect all local histories—of places in the state—and whatever materials for local history may be available in any form. Some of the old town histories are very valuable, and copies are becoming scarce. All town reports should be collected and preserved, and those of certain boards and commissions. The work of the trustees will doubtless produce a general increase of interest in local history—a most wholesome and desirable result. In many of the shore towns the descendants of the oldest families, although educated in the public schools, are almost entirely ignorant of the history of their own towns and of the part their ancestors had in it. Many of the teachers in the schools are no better informed on this subject. The lack of popular interest regarding it is often astonishing. In one of the towns the two hundred and fiftieth anniversary of the organization of the church came and passed without any observance or recognition whatever. There was not even a prayer-meeting, or any allusion to the date in the sermons or services either before or after it. I think that every town should prepare a brief compend, or manual, of the principal facts in its own history, and provide that it shall be studied and taught in the town schools. It would be the natural introduction to state and United States history. Once, at least, each year the schools should visit and examine the most important historic places in the town.

26. The neglect and desecration of many of the old graveyards in the shore towns is a matter for most serious regret. I have not mentioned all the instances that came under my observation. There were too many of them for separate description, and the story became monotonous. It is unaccountable that, in several cases, with vast areas of barren and worthless ground on every side, the citizens should have decided to run a public road directly through the old cemeteries, thus violating the graves of their forefathers and destroying the head-stones, by which alone the resting-places of their dust could be identified. The sites of some of the smaller early burying-places are perhaps irrecoverably lost and indistinguishable, but steps should at once be taken to mark and protect all that remain.

27. It was encouraging to find so many highly civilized men in the office of town clerk, and out of it. My thanks are due to the town officers and citizens in general everywhere.

The Pepino, *Solanum muricatum*.

WITHIN the last few years a novelty has appeared in the seedsmen's catalogues under the name of Pepino, Melon Pear, Melon Shrub and *Solanum guatemalense*. Its botanical affinities and its horticultural merits have been perplexing, and, therefore, Professor Bailey has tested the plant for two seasons at the Cornell Station, and in a late bulletin he gives an interesting account of it, the main points of which are here reproduced:

The plant is a strong-growing herb or half-shrub in this cli-

mate, becoming two or three feet high and as many broad. It has a clean and attractive foliage, composed of long-lanceolate, nearly smooth, very dark green entire leaves. It is a profuse bloomer, the bright blue flowers reminding one of Potato-flowers. But one fruit sets in each flower-cluster, and as this grows the stem elongates until it reaches a length of from four to six inches. The fruit itself is very handsome. As it ripens, it assumes a warm yellow color, which is overlaid with streaks and veins of violet-purple. These fruits are somewhat egg-shaped, conspicuously pointed, and vary from two and a half to three and a half inches in length. If the fruits are still green upon the approach of frost, they may be placed in a cool dry room, where, in the course of two or three weeks, they will take on their handsome color. If carefully handled or wrapped in paper, the fruits will keep until midwinter or later. The fruit is pleasantly scented, and the flavor of it may be compared to that of a juicy, tender and somewhat acid Egg-plant. It is eaten either raw or cooked.

Upon the approach of winter we dig up some of the plants and remove them to the conservatory or forcing-house. It is in the capacity of ornamental plants that they will probably find their greatest usefulness in this latitude. The habit is attractive, the flowers bright and pleasant, and the fruit—if it is obtained—is highly ornamental and curious. The plant will stand a little frost. It has not fruited freely at the station, however, although it blooms profusely, and efforts have been made to insure fruiting by hand-pollination. The anthers give very little pollen. Perhaps half the plants succeed in setting two or three fruits apiece. All the fruits raised have been entirely seedless, although the seed-cavities remain. The plant must be propagated by cuttings or layers therefore. The stock used was obtained from a botanical specimen from Florida and was not thoroughly dried.

This plant was introduced into the United States from Guatemala in 1882 by Gustave Eisen, of California. There has been much speculation as to its nativity and its true botanical position. At first it was thought by some to be a variety of the Egg-plant, but it is very distinct from that species. But the plant is by no means a novelty to science nor even to cultivation, for it was accurately described and figured so early as 1714 by Feuillée in his account of travels in Peru. He called it *Melongena laurifolia*. At that time the plant bore "several little lenticular seeds, one line broad." It was carefully cultivated in gardens, and the Indians ate it with delight. The taste is described as somewhat like a melon. Eating too heartily of it was supposed to bring on fevers. In Lima it is called Pepo. In 1799 it was again described and figured by Ruiz and Pavon. They described the fruit as "ovate, pointed, smooth and shining, white variegated with purple, hanging, of the shape of a lemon." They say that it was much cultivated in Peru, and added that it was propagated by means of cuttings. It was called "Pepino de la tierra." In 1785, Thouin, a noted French gardener, introduced it into Europe, and four years later Aiton, of the Royal Garden at Kew, England, named it *Solanum muricatum*. The specific name, muricate or prickly, was given in reference to the rough or warty character of the sprouts which spring from the root, and which are often used for propagation. And now, over a hundred years later, it has found its way to us.

Mr. Eisen's account of the Pepino will be interesting in this connection. "The Central American name of this plant," he writes, "is Pepino. Under this name it is known everywhere in the Central American highlands, and under this name only. But as Pepino in Spanish also means Cucumber, it was thought best to give the plant an English name. I suggested the name Melon-shrub, but through the error or the wisdom of a printer the name was changed to Melon Pear, which I confess is not very appropriate, but still no less so than Pear Guava, Alligator Pear, Rose Apple, Strawberry Guava, Mango Apple, Custard Apple, etc. . . . As to the value of the fruit and the success of it in the United States, only time will tell. The fact that I found the plant growing only on the high land where the temperature in the shade seldom reaches seventy-five degrees, Fahrenheit, suggested to me the probability that it would fruit in a more northern latitude. In California it has proved a success in the cooler parts, such as in Los Angeles city, and in several places in the Coast-range, and will undoubtedly fruit in many other localities where it is not too hot. . . . In pulp and skin the Pepino resembles somewhat the Bartlett pear, but in taste more a musk-melon; but it has besides a most delicious acid, entirely wanting in melons, and quite peculiarly its own. In warm localities this acid does not develop, and this fact is the greatest drawback to the success of the fruit. The fruit has no seed, as a rule. And in all I have found only a dozen seeds, and those in fruit which came from Salama, in Guatemala, a

place rather too warm to produce the finest quality of fruit." Last year Mr. Eisen writes that "it has only succeeded in Florida, but has there proved of considerable value."*

The greatest fault of the Pepino appears to be its failure to set fruit. Mr. Eisen states that in Guatemala it "yields enormously, 100 to 150 fruits to a vine four feet in diameter being nothing uncommon. I have seen it yield similarly in California, but whenever exposed to too much heat and dryness it is very slow to set fruit." He recommends that it be shaded if it refuses to set fruit. Martin Benson, Dade County, Florida, writing to the *American Garden*, says that he has had great success with it. "I counted the fruits on a medium-sized plant and found it bore sixty, of all sizes, from those just set to some nearly matured, and weighing upward of a pound. The fruit varies considerably, but averages about the size of a goose-egg. It requires cool weather in order to set fruit, and never does so excepting during a norther or other cool spell, when the fruit sets in great quantities." In the northern states it has always proved a shy bearer, so far as the records show.

The Pepino is an unusually interesting plant, and if it could be made to set fruit more freely in the north, it would be an acquisition for the kitchen-garden and for market. It is a good ornamental plant, and, altogether, it is deserving of a wider reputation.

Notes.

Messrs. Pitcher & Manda announce an exhibition of Orchids, Palms, Ferns and rare plants, to be held at the United States Nurseries, Short Hills, New Jersey, from February 29th to March 5th, inclusive.

Professor W. G. Farlow's paper on "Diseases of Trees likely to follow Mechanical Injuries," read a year ago before the Massachusetts Historical Society, has been published in a small pamphlet. It gives an untechnical account of the structure of tree-trunks, with useful directions for protecting trees properly, for pruning them and for preventing the growth of fungi, as well as an earnest plea for the planting and careful tending of trees in city and village streets.

The directory in charge of the Florida exhibits for the Columbian World's Fair has announced that among these will be a specimen of *Torreya taxifolia*, the rare tree which has made the region about the head-waters of the Apalachicola famous. The *Florida Agriculturist* adds that *Pseudo-phoenix Sargentii*, the rare Palm discovered in 1886 on Elliott's Key, and *Ficus aurea*, the Wild Fig of south Florida, should be included among the exclusive arboreal productions of Florida. *Ficus aurea*, however, is known to be an inhabitant of the Bahama Islands.

How subtle are the Japanese rules for arranging flowers and how arbitrary, according to our western ideas, may be shown by the numerical proportions which they usually observe between leaves and flowers in an arrangement of Irises. With three leaves they use one flower, with seven leaves two flowers, with eleven leaves five flowers, with thirteen leaves only three flowers, and with fifteen only two again. But when we examine pictures that show the results of the application of these rules, we are convinced that they have been dictated by a very true feeling for artistic effects of the most delicate sort.

It was not known until of late years from what plant bay-rum was prepared, but it is now ascertained, says the *Bulletin of the Jamaica Botanical Department*, that it is manufactured in Dominica from the dried leaves of *Pimenta acris*. Bay-rum is procured by distillation, and this in a very simple manner. The leaves are picked from the trees and then dried; in this state they are placed in the retort, which is then filled with water, and the process of distillation is carried on. The vapor is then condensed in the usual way, and forms what is known as "bay oil," a very small quantity of which is required for each puncheon of rum. The manufacture of bay-rum is carried on at the northern end of Dominica, and proves a very lucrative business to those engaged in it, as the plants are plentiful in this district.

Erfurt is one of the great seed-growing centres of Europe, and one firm there devotes a hundred acres to the raising of the seed of China Asters alone. A late number of the *Gardeners' Chronicle* contains a picture of Mr. T. C. Heimemann's Aster-farm, a great level, carpeted with flowers and stretching away almost as far as the eye can reach. Great care is said to be taken to keep the several types of these plants true to character and of uniform quality, and the competition among the

growers in Germany operates to maintain these features. The introduction of new types during the past ten or twelve years, among which the Comet Aster may be named as a striking example, has been remarkable. Early blooming is necessary to secure a good harvest of plump well-matured seed, and the finest and the most productive plants are said to be produced from seed sown about the end of March in frames. The seedlings, when large enough, are pricked out in prepared beds in the open air, where some protection is given them by night when required. Many growers transplant them again about the first half of June, when the plants are given abundant room to develop.

Dr. C. F. Millsbaugh, of the West Virginia Experiment Station, in a late bulletin, gives an analysis of many common weeds to show their comparative manurial value. They vary very largely in the percentages of nitrogen, phosphoric acid and potash which they contain, one of the Evening Primroses, for example, containing only one per cent. of nitrogen, while the Poke Weed contains nearly three and a half per cent. A dry ton of Poke Weed contains these elements to the value of \$22.00. It would seem, therefore, well worth while to make a compost heap of weeds and carefully save the Poke Weed, Bitter Dock and Thistle, which are the most valuable. The better method of preparing such a heap in an open field is to lay on the ground a base of fence-rails or poles, which will allow a circulation of air, and upon this to throw a load of weeds, and then scatter over them plaster at the rate of a hundred pounds per ton. Then place another layer of weeds and more plaster, and so on until the heap is of suitable size. When completed, the heap should be covered with earth or turf, and at the end of five days, unless it is wet, some water should be thrown on it to assist the process of decomposition. Not enough, however, should be used to leach through. The heap ought to be ripe enough to use after two months' standing.

Professor Byron D. Halsted's paper on "Eastern and Western Weeds," read last summer in Washington, has recently been printed in the *Bulletin of the Torrey Botanical Club*. It was based upon "the reports of a number of botanists and crop-growers throughout the United States, received in response to letters sent to them or questions asked through the public press," but the basis taken for a detailed comparison of eastern and western weeds was the weeds of New Jersey and Iowa, as Professor Halsted had lived in both these states and personally studied his subject there. His classification of weeds as "worst," "bad" and "indifferent," and again as annuals, biennials and perennials, shows that, as regards the weeds of Iowa, "in passing from the worst class through the middle class to the indifferent, the percentage of perennials rapidly increases." Nearly half the weeds in New Jersey are foreigners—130 introduced species having been enumerated there as against 87 in Iowa, and the increase being "mostly among the worst and bad sorts." On the other hand, while New Jersey counts 135 native weeds Iowa counts 210, but the species not common to both states are "mostly of the third-class weeds, native in large part to the prairie," which, as a rule, "quickly disappear when the land is placed under cultivation," and many of which, in localities where they do not grow so rampantly, would be highly esteemed for their beauty. In general, says Professor Halsted, the whole east, as compared with the west, "is overrun with a larger number of the most aggressive weeds—weeds that assert their ability to resist the forces of the cultivator and plant their banners upon the tilled ground, likewise annual weeds that stock the soil with a multitude of seeds ready to spring into life whenever an opportunity offers.

Spruces and Firs on the Maine Coast.

AS the traveler passes the boundary of the state of Maine, on his way northward, he is conscious of a change in the silhouette of the forest against the sky. The dome-like outline, the great rounded masses begin to disappear, and in their place arise the serried lances of Spruces and Firs, which, fine as they are in detail, are the despair of the painter from the rigidity of the serrated line which they present. Italian artists, accustomed as they are to swelling slopes, maintain that Switzerland is unpaintable because the forms of the mountains lack grace of curve, and are sternly defiant and hard in outline, and one is conscious of this same artistic defect as he contemplates the Maine landscape, with the sharp tips of its evergreens standing out against the clear distant sky.

The farther north one goes along the coast the more exclusive becomes the Conifer. The native Larch, or Hackmatack, mingles its feathery branches with those of its more rigid neighbors, its cones showing dark among the soft green tufts of leaves, and only the light-foliaged Birch diversifies the sombre groups of Firs with its shining stems, like a white-robed woman at a funeral.

As the traveler turns from the shore to the interior, deciduous trees of the hardier varieties become more numerous, but the prevailing character of the coast landscape is such as is portrayed in the illustration on page 101, which is from a photograph taken at Southwest Harbor, Mount Desert, Maine.

In the cool moist atmosphere which suits their development, Spruces and Firs grow with surprising rapidity, apparently without regard to nourishment from the soil. The rockiest hill-sides clothe themselves suddenly with tiny green forms which shoot up in twenty years into an impenetrable forest. Granite ledges seem no obstacle to their growth; the sprout splits the rock in twain and pushes up bravely to the light and air among its taller brethren. On stony ground the roots of Spruces run

along the very surface of the soil, drawing sustenance from dead mosses and the thin stratum of earth formed by decaying vegetation, and fertilized by bits of the fish dropped by the birds which roost in the tall tops. One of the features of a sea-side wood is the shells of sea-urchins one is sure to find among the cones which sprinkle the mossy carpet.

When a great gale comes the Spruces tip over, having no tap-roots, and they will go on flourishing for some years after they have fallen, with only the dirt that clings to their straggling roots to preserve the vitality of the tree. In a hurricane the Firs snap off, or their trunks are twisted and torn from their base by the whirling of a cyclone, but the Spruces are bowled over like a lot of nine-pins, and lie in winrows like a giant crop mown by some Cyclopean hand.

Very beautiful are these growing forests in their youth. The roots of the pre-existent trees, either cut or fallen, leave soft mounds clothed with the loveliest mosses, with gray white caps or scarlet bonnets or brown hoods for blossoms. Here early spring-flowers bloom and wild vines clamber, and the paths are glossy with the leaves of Wintergreen and Pipsissewa. The young trees are symmetrical masses of foliage from root to point, and natural paths wind between them in intricate mazes, with fairy rings of open ground between the conifers. Sometimes a brook tumbles along among the shadows, which is crossed by stepping-stones, that lead into still more mysterious depths of this miniature wood, in its perfection of individual beauty when the trees are about twelve or fifteen years old.

After that the stronger trees begin to shoot up and wrestle for precedence—the space becomes crowded, the lower limbs, lacking light and room enough, begin to lose their foliage, twigs and dead branches strew the ground. The wood takes on a more sombre character; blossoms disappear; the thickets grow more difficult to penetrate; the cheerful garden gives place to the forest, with its solemn dignity, its church-like stillness and gloom, its heavy panopies of gray pendent mosses.

Only the osprey and the crow frequent these solitudes. Heavily the sea-eagle flaps his mighty wings, as laden with his prey he slowly sweeps to his ragged nest upon the summit of some lightning-blasted Fir, whence come the screams of his hungry brood. In the openings of the forest grave circles of crows hold their parliament with loud discourse and surly wrangling.

Now and then a solitary raven flies low along the edge of the wood, uttering a hoarse and melancholy croak; through the tall trunks can be discerned the black waters of a sullen sea, and the monotone of its utterance as it breaks against the crags below mingles with the unceasing murmur of the forest. A furled white sail makes a spot of light amid the stretch of restless water, where a wave at intervals breaks into foam, but it disappears in the distance, and only the great Spruces creak and groan in the rising wind, and answer the challenge of the sea with mutterings of defiance. On the edge of the cliff the little red-cheeked cranberries glow amid their glossy leaves, and down below, in its rocky clefts, hung all summer with Hare-bells, the clean outline of the Rock Poly-pod is visible against the crumbling granite wall. Now and then a fragment of this crashes into the gnawing sea at its base, which ever scourges and tears at its foundations like an avenging Fury.

Lonely and terrible are the old woods on the wind-torn coast. Beside the light-houses that comfort the mariner are seen the bare scathed trunks of dead trees, all blown one way like sign-posts of destruction. The leaping waves seem ever striving to reach them, and these gaunt wraiths of trees take on eldritch forms, and seem to wave defiant arms at their watery enemies. But still the young Spruces and Firs grow and thrive upon the ruins of their ancestors, clothing the crags with verdure, and renewing daily the youth of the eternal forest, which braces itself afresh to the unending combat with the elements.

EVER since the Yellowstone Park was created the Secretaries of the Interior have had charge of it, and superintendents and other officers have acted under their authority. The successive Secretaries have given much time and consideration to this territory, and the best friends of the park have been satisfied with the care which it has received from these officers. On the 1st of February a bill was introduced into the Senate for the alleged purpose of incorporating the Yellowstone Park Company, but if enacted it would practically operate to surrender the park to four men, who are named in the bill, for twenty years, with the privilege of renewing their power for twenty years longer. The act is shrewdly drawn, so as to have an appearance of maintaining the rights of the park, while really it gives this company power to build hotels, to run cable-cars, to quarry stone, to manufacture brick, to use timber for building and fuel, and, in fact, to do what they please without any restraining power whatever. Hitherto it has been in the power of the Secretary of the Interior to grant all leases and to make all contracts, and the only safety for the park is to leave it under the care and authority of some person in high official position like a member of the Cabinet. One can hardly conceive of a more impudent demand than this one of four men for a monopoly of this immense territory and all its resources.

THE first annual meeting of the New York Carnation Society, which was held at Buffalo on the 16th of February, leads one to wish that similar societies might be formed and similar meetings held by persons specially interested in the cultivation of the Rose, the Chrysanthemum, the Dahlia and other flowers. Advances in horticultural art have usually been made by students who devote themselves to specialties of some kind. The general public are not warmly interested in the development of so-called florists' flowers—that is, flowers which are molded into a fixed form, and which are not considered to have any merit unless they conform to some rigid outline decided upon by a committee as to true and ideal form. But every lover of flowers is interested in what patient and careful attention will accomplish in the way of discovering the best methods of cultivation, of hybridizing, of combating diseases, of increasing vigor and prolonging the blooming season of good plants. At this first meeting of the Carnation Society there were discussions of the highest practical value about the Carnation Rust, the alleged deterioration of varieties, the best methods of propagation, and other equally important topics. It is only through long-continued and special study that we can learn the secrets of the growth of plants, and every organization that tends to direct intelligent attention to plants and their ways deserves the best wishes of every one interested in horticulture.

Notes on Nomenclature.

QUERCUS KELLOGGII, Newberry.—The oldest name applied to this species is that of Torrey, *Quercus tinctoria*, var. *Californica*, published in 1856 (*Pacif. R. R. Report*, iv., 138), here being considered only a variety of the eastern Quercitron Oak, and antedating the *Q. Kelloggii* of Newberry (*Pacif. R. R. Report*, vi., 89, 28, f. 6 [1857]) by one year. As no question now remains as to the specific distinctness of Kellogg's Oak from its eastern relative, there appears to be no good reason for not following Cooper, who was first to raise Torrey's name to specific rank (*Smithsonian Report* for 1858, 261 [1859]), *Q. Kelloggii*, Newberry, would, therefore, become *Q. Californica*, Cooper.

It is perhaps to be regretted that the specific name, *Kelloggii*, can be no longer retained in honor of the one who studied the Pacific Oaks so carefully; it is certain, however, that as with the "Douglas Spruce" (*Pseudotsuga Douglasi* becoming *P. taxifolia*), "Kellogg's Oak" should always stand first as a vernacular name.

QUERCUS TINCTORIA, Bartram.—Bartram's name for the Quercitron Oak, although long maintained for this species, seems nevertheless not to be legitimate, nor by any means the oldest one applied to the tree. Aside, moreover, from the fact that it is antedated by others, the name itself is not even founded on a diagnosis of the species; yet the tendency among fair-minded botanists and zoölogists to interpret rather the intent of nomenclatural codes than to adhere too rigidly to the literal meaning of a prescribed law, would perhaps enable us to still retain *tinctoria* as a specific name, although founded only on the following statement:

"Gigantic black Oak, *Querc. tinctoria*; the bark of this species of Oak is found to afford a valuable yellow dye. This tree is known by the name of Black Oak in Pennsylvania, New Jersey, New York and New England. . . . I can assert that many of the Black Oaks measure nine, ten and eleven feet in diameter five feet above ground" (Bartram, *Travels*, p. 37 [1791]). Doubtless the large size and production of a yellow dye, aided by a system of seclusion, points circumstantially to the Quercitron Oak.

There are, though, cases in which the first name, similarly established, has been discarded for a later one secured by a strictly technical diagnosis; so that those inclined to follow the letter of the code may not complain if *tinctoria* be set aside for an older if not the oldest name.

The oldest name suspected to belong here is the *Quercus velutina* of Lamarck (*Encycl. Meth. Bot.*, i., 721), published in 1789, two years previous to Bartram's *Quercus tinctoria* (1791). Koch (*Dendrologie*, ii, pt. 2, 68) took up Lamarck's name, but seems not to have been followed by any subsequent writers. Professor Sargent questions the validity of *Quercus velutina*, and cites it as a synonym of *Quercus tinctoria* (*Cat. For. Trees*, 149). But while there must always remain doubt in the identification of names in the absence of good figures or specimens, there seems to be as good reason for taking up *Quercus velutina*, Lamarck, as for still retaining *Quercus rubra* of Linnæus. Of *Quercus velutina*, Lamarck says, "*Quercus foliis obovatis angulatis subtus brevissimè lanatis, angulis seta terminatis*" (l. c.); of *Quercus rubra*, Linnæus says, "*Quercus foliis obtuse-sinuatis setaceo-mucronatis*" (*Spec.*, ed. 1, 996). Certainly the foundation of Linnæus' name—which as the oldest no one thinks of disturbing—can as well be questioned as the propriety of establishing Lamarck's *Quercus velutina*, the oldest name for the Quercitron.

An older name also for this Oak than Bartram's *Quercus tinctoria* (1791) is the *Quercus discolor* of Aiton (*Hortus Kewensis*, iii., 358), published in 1789.

QUERCUS FALCATA, Michaux.—As already pointed out by Professor Sargent (*GARDEN AND FOREST*, ii., 471), there are two or three other names included in the synonymy of this species which are much older than Michaux's *Quercus falcata* (1801). Wangenheim's *Quercus cuneata* (1787) has, however, been selected as the only authentic name to supplant Michaux's *Quercus falcata*. Of the identity of *Quercus cuneata* there can, of course, be no doubt, based as it is on a figure of a well-known form of the plant. But before passing this point, it may be advisable, since the inconvenience of a change must be made from *Quercus falcata*, to inquire if there is not sufficient reason for taking up Marshall's *Quercus nigra digitata* (1785), the oldest name supposed to have been applied to the Spanish Oak. His *Quercus rubra Montana* may also belong here, but occurs later in the *Arbustum*. Of the two descriptions, the first and the one under "*Quercus nigra digitata*" seems to be the more suggestive of the species Marshall had in hand, and under this caption, "*Quercus nigra digitata*—Finger-leaved Black Oak," he says:

"This grows naturally in low lands, rising to the height of thirty or forty feet, with a trunk of considerable thickness, covered with a rough blackish bark. The leaves are sinuated, or divided toward their extremities into two or three pretty long, somewhat finger-shaped, lobes of unequal length, with others shorter, sometimes at the sides; all of

which end in a bristly point. The acorns are small, but the cups pretty large."

What other of our eastern species Marshall could have had in hand than the common trilobed form of the Spanish Oak is difficult to imagine, nor does it require a stretch of imagination to suppose that the name and description apply to this Oak. If this be conceded, the *Quercus falcata* of Michaux becomes *Quercus digitata*, Marshall.

New England Parks.

THE MIDDLESEX FELLS.

THOUGH the Middlesex Fells are only a park in prospect, the hope is so confidently entertained that they will be acquired by the state for public purposes, that I take the liberty of classing that natural pleasure-ground among those which already belong to the public by gift or purchase.

Already a movement is on foot to acquire the four thousand acres of rolling woodland which are included in this region, to retain it as a breathing-place for that greater Boston which is in time to surround the important peninsula, as Paris encircles the island in the Seine, and as London surrounds "the City." This great scheme of consolidation commends itself to the imagination for its splendid possibilities, and as we see Boston extending itself throughout its charming suburbs, with which it keeps itself far more in touch than New York and Philadelphia do with theirs, the time seems not far away when the city will include them entirely, and while a system of prefectures shall provide for the local government of the outlying departments, the towns within a twelve-mile radius may come under the wing of a central municipal government. Politically one cannot wholly be reconciled to this fine scheme, but theoretically it has a picturesque splendor, and if it is ever achieved the Middlesex Fells will be an important centre for the numerous towns that border upon the region—Melrose, Medford, Winchester and Malden all abutting upon the open spaces which will in time be so precious to the city-dweller.

What are the Middlesex Fells? is often asked, now that this felicitous title, first applied to them some twelve years ago by that true lover of nature, Mr. Sylvester Baxter, has passed into such popular acceptance that they even have a local habitation as well as a name, in a small railway-station known to the succinct Pathfinder as Fells.

These fells are a series of low, well-wooded hills, the highest of which is some 300 feet in altitude, which are easily accessible from the western division of the Boston and Maine Railroad, from either Malden, Medford or Melrose. To visit them extensively and thoroughly in a short time a carriage is necessary, and by alighting at Melrose, where one can easily be procured near the station, a few hours will enable one to explore them satisfactorily. To those who live near by they afford charming possibilities for tramps and climbs, already discovered by the Appalachian Club, and as good roads through them abound, they can comfortably be explored on a bicycle, with occasional digressions on foot from the beaten track.

The first point of note in the Melrose section is Pine Bank, the property of Mr. E. S. Converse, where, among other interesting features, a curious glacial moraine, covered with fine old conifers, is interesting to visit. This ridge of land, deposited by some long-departed glacier, carpeted thickly and softly with Pine-needles, slopes on either hand to ravines, also well wooded with Pines and Hemlocks. The long, straight walk under their sighing branches is very beautiful, and the formation of the moraine is full of interest and suggestion.

The wildness of this part of Mr. Converse's estate, the pleasing views from its elevations, and the beauty of the trees, render it very attractive. I am told that should the Middlesex Fells be acquired by the state, it is the purpose of Mr. Converse to give a portion of this valuable property to the public; another instance of the noble generosity of the citizens of the Commonwealth of Massachusetts.

From this point a short drive brings one to the Cascades, a fine natural feature. Leaving the high-road, a climb through a grove of Oak-trees brings one to the foot of an eminence, from the top of which a stream comes tumbling down over a rocky cliff, dripping from ledge to ledge of the fern-hung rocks mossy with the perpetual moisture, and rippling noisily away in a stony brook below. This cataract, which in spring, when swollen by the melting snows and frequent rains, must be quite wonderful, was, when I saw it, so shrunken by the long drought that it was but a Staubbach of a fall, and

showed little more than a trickle down the face of the massive rocks, picturesque with their drapery of Ferns and Lichens.

In a park, with proper treatment, these cascades would be very effective, and paths might lead easily to the top of the hill, which now can only be scaled by some rather rough scrambling.

Another charming object in the Fells is Spot Pond, a lovely sheet of water bordered by woods, along which the road leads in attractive windings that give varying views of distant hills behind the blue water. In the neighborhood of the pond is the Langwood Hotel, a spacious hostelry with large verandas enclosed in glass, which is open to visitors at all seasons of the year. Here we dined comfortably at a table artistically strewn with brown Chesnut-leaves, and had a chance to appreciate the taste and skill which have presided over the appointments of this pleasant inn.

But of all the many points of view in the Fells, with its numerous drives and walks, affording constant variety of landscape, that which we obtained by climbing Bear Hill was the most beautiful and striking. This is an elevation of some three or four hundred feet, to which one climbs through thick woods, up a steep slope, encountering fences and snags by the way, but coming out at last upon a cleared summit from which there is a famous outlook.

Seen of a soft day in early November, with the distant hills bathed and glorified in the purple haze of Indian summer, the chimneys and towers of distant towns took on mysterious meaning, while Tufts College, upon its eminence, might well be mistaken for an imposing castle. Banks of hills rose one behind the other in tender diaphanous outline, the Milton Hills merely a hint against the sky, and the State-house dome a glimmering spark of fire amid the forest of pale spires that represented Boston. Translucent delectable mountains encircled the horizon, among which dim familiar peaks were visible. Monadnock and Wachusett were but mountain dreams in this vision, where the tiers of opalescent highlands, bathed in the low sunlight, were transfigured by the atmosphere of the dying year.

Near at hand gleamed the waters of Winchester reservoirs and Spot Pond. The woods of Lynn stretched away like a wilderness in the middle distance, while the neighboring summits of the Fells, crowned with trees and dwellings, clustered in undulating surface of varying heights about Bear Hill, from which the eastward scope of greater Boston could be clearly discerned, while up its steep sides clambered the Pines and Hemlocks, the Oaks and Maples that clothed it in a cloak of russet, faced with green. The top of the hill was bare of trees, but well furnished with masses of wild shrubs hung with fruit. The Privet showed its dark berries; the Berberies were gay with ruddy clusters; the Sumachs glowed with crimson leaf and deep red spikes of fruitage; mosses grew soft and green under foot; the Scrub Oaks clustered in brown groups, and acorns lay scattered on the ground. The tints, all soft and harmonious, ran through a scale of russet and copper-color to the duldest red. Stiff little Junipers rose here and there in the symmetry of early youth, some bluish and some of a deep yellow-green. The hill-side was slippery with the fresh-fallen leaves, which crackled under foot; vistas opened through the wood as we climbed and descended the hill that offered points of view in different directions, each picturesque with a new beauty.

An autumn day in the woods is one of the delights of existence; the cool fresh air renders exercise a pleasure; the transitory brightness makes each effect more precious, as if it were to be the last. The beauty of our atmosphere at this season is unrivaled even in Italy, where the same glamour is seen at other seasons. Moisture and smoke are the secret of the ineffable colorings of the Bay of Naples, for when a keen clear wind drives away the puffings of Vesuvius the sharp black volcanic outlines lose their beauty, and stand up in all their barren harshness, cold and awful and forbidding.

So when distant woods are burning and the air is humid and chill, our austere New England puts on a Neapolitan robe of azure and violet that rivals the hues of Capri and Amalfi. Her granite hills are transformed to porphyry and jasper, her prosaic outlines grow soft with strange suggestiveness. A far-off chimney becomes a campanile; a factory is glorified into a fortress; an institution looms like a chateau. There is a joy in the dim silhouette of distant roofs against the sky, an elevation in the curve of dome and upward lift of spire, a hint of mountain-ranges in a row of misty hill-tops.

What the imagination is to the mind, the atmosphere of Indian summer is to a Massachusetts landscape. Unreal, you say; but who shall dare to question the truth of Nature viewed, as she best loves to show her coquettish face, half-

veiled in violet gauzes? For Earth herself in her seductive moods loves to confound the realist, and to force him to lift his microscopic eye to behold her splendors with a vision too dazzled to dwell upon the scars and wounds man makes upon her noble bosom.

In that breadth of vision which excludes detail, in that elevation of view which reveals the type and not the individual, the grand sweep of the hills, and not their gravel-pits and quarries, the mighty mass of the forest, and not its unsightly clearings and half-dead trees, can Nature's highest beauty alone be revealed, and her loftiest aspects brought to light.

This is truth poetized, not the every-day appearance of a prospect, but that vision which, under rare conditions, comes to reveal to man the higher loveliness oftenest hidden from view, but none the less a true perception for him who has the power to sing his song, or paint his picture with the notes or color drawn from the inspiration of a fleeting moment, which he has the gift to make permanent.

Thus that November afternoon the Middlesex Fells became an enchanted region of pale sunlight and shadow, such as we might seek in vain to find on another occasion. Not always can it be bathed in such misty tints, or brightened with such mellow autumn hues as made its distances dreamy, and its foregrounds rich for the group that were privileged to see them in gala attire on that fortunate day. But as a possession for the state it will ever have a serious value, this open, breezy varied space of hill and valley, lake and woodland, which it would be a misfortune to sacrifice to any purely utilitarian idea.

Its natural ruggedness renders it difficult for building, impossible for agriculture, so that it has been preserved in natural wildness and beauty for this very time, when the best interests of the state demand that it should be made a reserve that will add incalculably to the real value of the neighboring towns, which can rejoice in its fine, health-giving opportunities, and gain new dignity from their neighborhood to so noble a pleasure-ground.

Hingham, Mass.

M. C. Robbins.

Spring in West Virginia.

THE advance-guard of spring reaches West Virginia early in February, and we celebrate its arrival with a feast of Water Cresses, which are as grateful to snow-wearied eyes as to the palate. The birds know very well that spring is coming, for in February the cardinal grosbeak whistles boldly on every frost-free morning, and the bluebird takes you into his confidence in his quiet fashion to say that the season of flowers is really at hand. The shrubberies on this 19th day of February are full of swelling buds, and even some insect life is discoverable here and there, and spider threads are seen thrown from one limb to another. Very striking is a low clump of Honey Locusts, the deep red spines of which make an effective contrast to the striped bark of the branches, a light gray on olive-green and very smooth and satiny in texture. These curious waves and markings are confined to the young growth and are conspicuous now. Later on, in the exquisite delicacy of its foliage, the red leaflets matching the thorns in color, it will rival any of the greenhouse Acacias. The Hypericums are already leafing out and *H. aureum* is fairly covered with its stiff linear leaflets, dark green with red and orange tints on the latest comers.

Wall-flowers are in bud, bulbs are peeping through the ground, some of the early Hyacinths which stand in a sheltered nook are already well advanced. *Spiræa prunifolia* shows many tiny leaves, while *S. Thunbergii* is covered with knobby flower-buds, as are some of the *Cydonias*, while others show a few blood-red leaves just starting, and they are almost as pretty as the blossoms. *Caragana altagana* shows a green rosette here and there, and is only waiting for two or three warm, sunny days to open more of its curious leaf-buds, which look like little blotches of green paint scattered over the branchlets. Among the flowers, Crocuses are following the Snowdrops, and *Chionodoxas* are hard after them, with the earliest Jonquils, Daffodils, Violets and the lesser Periwinkle almost in sight. These modest blossoms are the ones which the flower-lover prizes above any of the later, more abundant and more gorgeous blooms which the lavish month of May brings with it.

It is a good plan to have a space in the shrubberies devoted to the March bloomers, some of which are found in very few gardens. There is a very early-blooming *Rhododendron*, *R. Dauricum*, that is not planted half as often as it should be. *Daphne Mezereum* shows with us the first rosy bloom of the year, the predominating color for early spring flowers seeming to be yellow, purple and white. *Daphne Genkwa* is a

charming plant of slow growth and fragrant violet-colored flowers, and probably the sweetest shrub that blooms in March. Then there is the Leather-wood (*Dirca palustris*), which grows wild in our woods, displaying small yellow bunches of flowers about the time that the Marsh Marigolds brighten the forest-pools with their gold. This shrub is offered by some nurserymen, and it is of easy cultivation away from its native habitat. *Jasminum nudiflorum* is a graceful shrub of early bloom, and cheerful in spite of its weeping habit. It is deservedly a favorite with designers of parks, and is much used about the public buildings in Washington, where it celebrates Easter Sunday after a sunny fashion peculiar to itself. *Prunus spinosa* and *P. Pissardi* bloom here late in March and are rather earlier than the *Forsythias*.

In the wild garden the Blood-root, Saxifrage and Twin Leaf will bloom as the earliest Fern-fronds are unrolling, and they are quickly followed by *Hepaticas*, in their woolly overcoats, the first *Anemones* and the fragrant *Epigæa*, which some people are able to coax into forgetting its native haunts and blooming in civilized gardens. On the very first of February, which was a genial day, we found reddish brown barren catkins two inches long, and tiny unopened pistillate flowers on our Japanese Alder, and these gave as keen pleasure as the bloom of a favorite Rose-tree in June. These catkins are far in advance of all the flowers of our other trees. Scarlet Maples, Aspens, Willows and Hazels are growing more interesting as the days lengthen, but to this Alder belongs the glory of being the first tree to bloom in spring.

Every day we watch the earliest bloomers among the shrubs for signs of growth. *Xanthocerus sorbifolia*, which the youngest member of the family will call rhinoceros, receives much attention. It has not bloomed yet, being, indeed, only eighteen inches high, and it is not likely that it will gratify our curiosity for another year, but it is said to produce blossoms when very small. *Chimonanthus fragrans* is also of much interest, as it has never been seen in bloom here. The red-branched *Cornels*, the yellow-stemmed *Forsythias*, the green twigs of Scotch Broom and the Japanese *Corchorus* are also attractive, and the bark grows brighter on them all as the buds begin to swell. *Lonicera sempervirens* was the first of all our plants to show the tender green of its spring foliage.

Rose Brake, West Va.

Danske Dandridge.

Plant Notes.

Some Recent Portraits.

The February issue of the *Botanical Magazine* contains portraits of the great Javanese *Primula Imperialis* (t. 7217), a noble species, producing immense leaves and tall scapes, with many whorls of orange-colored flowers.

Hydnophytum Forbesii (t. 7218), a representative of the wonderful group of epiphytic plants, peculiar in their tuberous root-stalks, which form nests for certain species of ants. There are two principal genera of these plants, natives of the Malayan and Pacific coasts and islands, both belonging to *Rubiaceæ*, and closely allied one to the other. They are *Myrmecodia*, with eighteen species, and *Hydnophytum* with thirty, and they were mostly discovered by the distinguished Italian botanist Beccari, who has bestowed upon this group the appropriate name of *Piante ospitricce*. The tuberous rhizome of *Hydnophytum Forbesii* is lobed, echinate, and produces short stems with subsessile, obovate, obtuse leaves, and axillary, short-stemmed flowers with a short calyx and an elongated, graceful, cylindrical, white corolla. The fruit is ellipsoidal, bright red, drupaceous, slightly compressed and two-lobed at the apex. *Hydnophytum Forbesii*, which is certainly one of the most curious and interesting plants recently introduced into cultivation, was discovered in New Guinea by Mr. Forbes, author of *A Naturalist's Wanderings in the Eastern Archipelago*, who, in 1886, sent it to the Royal Gardens at Kew, where it flowered three years later, and again last year.

Begonia glaucophylla (t. 7219), a plant now well known in gardens, but of unknown origin and history, and possibly a hybrid.

Vicia Narbonensis (t. 7220), a native of eastern Europe and western Asia, and chiefly interesting for the fact that it has been supposed to be the original form of the common

Fig. 17.—A Spruce Forest on the Coast of Maine.—See page 97.

bean, a fact which De Candolle, in his *Origine des Plantes Cultivées*, does not find supported by sufficient evidence.

Neobenthamia gracilis (t. 7221), a singular terrestrial Orchid, a native of eastern tropical Africa, with long tufted sparingly branched stems, which attain a height of four

feet and which are clothed almost throughout with grassy leaves, and terminate with a raceme of small white flowers, with a short, hardly spreading perianth, and a lip spreading from the base and slightly recurved above the middle. *Neobenthamia*, a genus which serves to com-

memorate Mr. Bentham's labors in revising the genera of Orchids for the *Genera Plantarum*, was discovered by Sir John Kirk in the Zanzibar kingdom, and was sent by him in 1884 to Kew, where it flowered in 1890.

Foreign Correspondence.

London Letter.

THE last annual meeting of the Royal Horticultural Society was remarkable for the tone of satisfaction which pervaded the proceedings. The President, Sir Trevor Lawrence, announced that "the affairs of the society were in a thoroughly satisfactory condition," while Professor Michael Foster, an ex-member of the council, congratulated the society on the greatly improved outlook which was evident in the report, and upon the good work done by the present council. The society has paid its way, has increased its constituency by several hundreds in the year, has issued a valuable series of horticultural papers in its journal, and has held numerous exhibitions and conferences. As Baron Schroeder expressed it, the society is growing rapidly and will soon burst its skin, when he anticipates it will assume that position among the industrial societies of this country which it is now better qualified for than it has been at any time within the last twenty-five years. This improvement is solely due to the determination of the society to mind its own business, which is that of promoting all matters that tend to improve and develop horticultural art. There was a time in the history of the society when it went far beyond this, and as a result it not only found itself in financial straits, but it lost the sympathy and co-operation of the great body of horticulturists. The President alluded to the want of a suitable exhibition-hall and offices, expressing at the same time a hope that the society would be as well provided for in this respect as the horticultural societies in the United States are.

An exhibition of plants and flowers was held on the same day, and proved of exceptional interest and attraction. All the available space was filled with groups of beautifully grown Cyclamens, Primulas, New Holland plants, stove-plants, Orchids and fruit. Messrs. H. Low & Co., of Clapton and Enfield, are endeavoring to revive the cultivation of hard-wooded greenhouse-plants, such as Boronias, Correas, Acacias, Pimelias, Chorozemas and Eriostemons, which were a principal feature in English gardens a generation or so ago. Mr. Cannell marks the progress made, chiefly by himself be it said, in the improvement of the popular Chinese Primrose. The Messrs. Walker, of Hounslow, do the same for Cyclamens. No greenhouse-plant is more beautiful or more valuable than the Persian Cyclamen when it is well grown; but, as a very clever London grower remarked last year, although everybody knows their value and attempts their cultivation, it is only very few who have the luck to succeed. Orchids predominated over everything else shown. Large groups from the principal growers and interesting collections from various amateurs were numerous and full of attraction for connoisseurs. Among the notable specimens was *Phalænopsis Brymerianum*, a beautiful plant, with large healthy leaves and a strong flower-spike, from Messrs. Low & Co. This is one of the rarest of the Moth Orchids, only two or three others being known in cultivation. It is like *P. intermedia* in general characters, differing chiefly in being larger and darker-flowered. The variety of *P. Schilleriana*, recently named *purpurea*, was also exhibited by the Clapton firm. It differs from the type in being a shade darker in color. *Cymbidium Hookerianum*, a beautiful species rarely seen in flower, was shown, the spike having flowers larger than those of *C. giganteum*, with broad fleshy pea-green sepals and petals, and a large spreading three-lobed lip, colored creamy white, spotted and tinged with crimson.

Cypripedium Lindleyanum is a species with broad stout leaves, glossy green, margined with brown, and an erect

spike, a yard high, bearing large boat-shaped green bracts and curious brownish green flowers. It is a native of British Guiana, and is synonymous with *C. Kaietorum*. Various new hybrid *Cypripediums* were also shown, *C. Hera*, from Messrs. Veitch, *C. Juno* and *C. Ceres*, from Mr. Drewett, being awarded certificates. The first-named is a grand plant, the flowers enormous in size, well formed and attractive in color. It is the offspring of *C. Boxalli* and *C. Leeaanum*. *Lycaste Youngii*, as exhibited by the President, is a beautiful Orchid. It bore fifty flowers, not unlike those of *L. aromatica*, but brighter yellow and longer in the peduncle.

Among *Cattleyas* I noted some most beautiful varieties of *C. Percivaliana*, one with white flowers, named *alba*, being the rarest, but not the prettiest. A white variety of *C. Trianae*, some grand blooms of the rather refractory *C. speciosissima*, and a very dark-colored variety of *Lælia anceps* were exceptionally good. The large-flowered distinct *Oncidium Loxense*, which is one of the finest of the macranthum section, *Odontoglossum ramosissimum* and *Oncidium splendidum* were represented in excellent form, the *Odontoglossum* much better than I thought it could be. Evidently this is a very variable species. A new hybrid *Zygopetalum* named *Leucochilum* was shown by Messrs. Veitch, the raisers, its parents being the diverse *Z. Burkei* and *Z. Mackayi*, and several new hybrid *Dendrobiums* were submitted for certificates, and in some cases obtained them. The pretty little alpine, *Oncidium Phalænopsis*, was shown in considerable variety by Messrs. Sander & Co. In my opinion this is one of the most charming of small Orchids for the cool house. It often fails under cultivation because it is kept warmer than is good for it. From the same firm came *Epidendrum Watsonianum*, a species remarkable for its large pear-shaped pseudo-bulbs, spikes as thick as a man's thumb and of great length; the flowers are like those of *E. verens* in shape and size, but colored apricot-yellow, mottled with green, the tip being white, with rosy spots. *Disa Cooperi*, from Natal, was represented in the St. Albans group by a strong plant bearing a spike eighteen inches high of yellowish green flowers, in which the fat upward projecting spur is extremely odd. *Odontoglossum Edwardii* and a variety of it named *Ioplocen*, the latter very fragrant, and with longer sepals than the type, were conspicuous, the rich violet-purple of their flowers being exceptional among Orchids.

Bertolonias were exhibited by Mr. F. Bause, the well-known raiser of hybrid *Dracænas*, *Coleus*, etc., in much grander colors and vigorous health than I had ever seen them. Mr. Bause is almost a magician in the way he manages many plants. These *Sonerilas*, for instance, were in four-inch pots, yet they were ten inches high, had leaves as large as an ordinary sheet of note paper, and colors as rich as rubies. I asked him what the manure was. "Oh, common soil, just; you merely want to keep them close to the glass in a warm little house, don't coddle them, and don't let them flower." He saw no reason why *Bertolonias* should not be grown two feet high! Kew exhibited a very large head of flowers of the new *Brownea Crawfordii*, which was declared to be the finest of all *Brownæas*; a spike of *Aloe supralævis*, mistaken by most people for a "grand new *Kniphofia*"; *Greyia Sutherlandii*, the beautiful crimson-flowered Saxifragaceous shrub from Natal and *Hæmanthus magnifica*. Messrs. Veitch sent a basket of plants in flower of the new *Lachenalia Aureliana*, which is simply a bright-colored form of the old *L. pendula*. Some pretty specimens of trees and shrubs in flower, said to be from the open ground, were contributed by the same firm. They included *Amygdalus Davidiana*, with its variety, *alba*, and *Lonicera Standishii*. These would be worth growing largely for forcing in winter.

INTERNATIONAL HORTICULTURAL EXHIBITION.—Preparations are being made for what it is hoped will prove a comprehensive exhibition of gardens, garden products, garden art—of everything, in fact, appertaining to horticulture. It is to be held on the grounds which were prepared some years

ago for the American Exhibition held in London, and which have since been annually devoted to other exhibitions from Germany, Italy, etc. According to the prospectus, this exhibition, which is to open in May and continue till October, is to display the state of progress of horticultural science, taste, resources, implements and plant culture at the present date, and, in addition, the various departments and exhibits will serve as models for every one who loves a garden. Examples of the gardens of all ages will be prepared, including restorations of the ancient gardens of Egypt, Greece and Rome; copies of those in China and Japan, and types of the Baronial, Italian, Tudor, Jacobean, Georgian and Victorian eras. A large sub-tropical garden will also form a feature of the attractions offered. The tea-gardens of India and Ceylon will be represented, illustrating the growth of the Tea-plant, etc. Arrangements have also been made whereby foreign countries will co-operate to show the progress in horticulture in their respective lands. Flower and fruit shows, special exhibits of American plants, Orchids, etc., will be held periodically. Lectures on practical gardening will be given regularly. Pictures and photographs and a reference library are being collected. The scheme is ambitious enough, and if it can be anything like accomplished it can scarcely fail of success. The chairman of the executive is Mr. H. E. Milner, F.L.S., who practices as a landscape-gardener in England, and whose book upon this department of horticulture was published about a year ago.

The Hardiness of the Satsuma Orange.

HAVING been deeply interested in this Orange, the hardiness of which has been so much talked about, I have from time to time written notes of its encouraging behavior here. I have now to record that it has reached the limit of its hardiness with full exposure. My trees were purposely planted on the most exposed spot I could select, a hill-top 400 feet above tide, which has the unbroken sweep of the north wind for miles. In the winter of 1890-91 the lowest temperature noted was nineteen degrees, Fahrenheit, and no harm was done to foliage or wood. January of the present year was a cold stormy month, and the trees were subjected several times to this same and a little lower temperature. But on January 26th the mercury suddenly fell, with a cloudless sky, to sixteen degrees by the sheltered thermometer, and several degrees lower by a thermometer exposed in the air near the trees. The result is that they are badly cut, and the young shoots killed. It would seem, then, that the extreme cold these trees will endure without harm is from eighteen to twenty degrees above zero, so the hope that they might prove entirely hardy, as has been suggested, "as far north as Delaware," is doomed to disappointment. They seem to be just about as hardy as the Fig. Fig-trees of the same age subjected to the same exposure as these Oranges are killed-back to about the same extent, while Figs a few yards away south of the hill-top, and protected by Pine-boughs stuck along between the rows, are entirely unharmed. This indicates that the Satsuma may be grown with complete success here in sheltered places and in our coast country from Morehead to Wilmington and about Newbern. Wherever, as in our coast plain, the *Gardenia florida* grows into a large shrub in full exposure, there the Satsuma will grow well, especially as the black peaty soil there will suit it better than our red clay. We have *Gardenias* growing unharmed under the shelter of our college walls, but there is little doubt that they would have been killed to the ground had they been in company with the *Satsumas*. Our trees are on the stock of *Citrus trifoliata*, and on this stock they will probably remain mere bushes, yet this makes it more easy to protect them, and in any sheltered spot where the Fig and *Gardenia* stand unharmed I have no doubt they can be grown.

Not far away from our *Satsuma* Oranges, but sheltered by buildings, we have a group of *Olivives*. The largest of these, a *Nevadillo Blanco*, in the centre of the group, is killed outright, while those on the outside have not even lost their leaves. These trees were planted only last spring, and those that survive may be able to endure greater cold hereafter. An *Ipomoea* from the lower Rio Grande (L. Texana), with a hard woody stem as stout as one's wrist, is killed to the ground, if not entirely dead, while a *Century-plant* (*Agave Americana*) on

the hill-top near the Oranges has lost only its outer leaves. *Pittosporum Tobira* shows not the slightest sign of injury, nor do any of the plants in my hedge of *Citrus trifoliata*.

Of course it is too soon to estimate the full amount of damage the winter may cause, as the sudden reverses of our spring are now to be encountered, but I think it is evident that the *Satsuma Orange* will come through in a battered condition.

Raleigh, N. C.

W. F. Massey.

Pyrethrums.

WITHIN the past few years both the double and single varieties of these fine border perennials have been improved to such a degree that it is hard to decide which ones to choose out of the long lists catalogued by dealers, especially since the new and high-priced varieties are naturally described as the best ever offered. It is always safe, however, to begin with well-tried kinds, and add the newer ones later if they are desired. *Pyrethrums* have met with much favor among hardy plant growers quite recently, as it is not very long since the fact of their hardiness was announced as a discovery in some gardening papers. There need be no longer any doubt as to their ability to winter in safety, but the way to insure this is to plant them in spring, so that they are well established by fall. The one thing *Pyrethrums* dislike of all else is disturbance of the root; once established and let alone success is certain. They seem to have little preference as to soils. I have grown them equally well in heavy soil and in a very sandy and dry one. The single varieties, especially the colored ones, are most in demand now, and for use as cut flowers they are far preferable to the double kinds. Even for border decoration the double varieties have a somewhat lumpy appearance when in bloom, and the first rain gives them a disheveled air, while the single flowers stand up fresh and bright. For both these reasons the double varieties are gradually making room for their more natural and graceful relatives, which present at the same time the oldest and most recent phases of the development of *Pyrethrum roseum*. The original is a native of the Caucasus, and is one of the plants from which is obtained the insect powder of commerce.

Some brief notes on propagating the most desirable varieties will explain the system which I have found satisfactory. By using it 300 plants were obtained from twenty in one year after they had been imported, and each of the 300 was better than the originals at the time of receiving them; for *Pyrethrums* are extremely difficult things to import successfully. As soon as frost leaves the ground these plants are among the first to show signs of growth, and when the first small leaves are developed the clumps should be lifted carefully and the soil shaken or washed off the roots, when it will be seen that all these young shoots may be easily severed from the root-stock, many of them with roots attached. Others may have no roots, and these may be placed in the propagating-bench, where they will speedily root, and when they may be potted in three-inch pots and carefully nursed for a few weeks before planting in the open ground. Those shoots that have roots when detached from the parent plant may be potted and placed at once in a cold frame, where they will grow on as if nothing had happened, and will even produce flowers in their season, but these are best pinched off as soon as they show, as this will induce the plant to make side shoots and become a much stronger plant for the next season. This method of propagation is very simple, and with a cold frame even a novice may increase plants in this way if he begins in time—that is, before the plants have made too much growth. If the work is delayed until the leaves are more advanced, and the sunshine is stronger, the plants will require shading, which will weaken them. The winter cold has few terrors for established *Pyrethrums*, but a hot dry summer after first planting them is most trying.

Pyrethrums, like most other hardy plants, may be easily raised from seed, and is a good way to form a collection quickly where they are required in quantity for cutting purposes. Named kinds may be acquired as chances offer. It seems scarcely necessary to name any kinds as being better than others. I have found that both French and English raisers have a set peculiar to themselves, and there is very little, if any, choice between them. A list taken from all would be too large for the needs of most gardens. It is quite difficult to obtain a good named set without importing them, which is perhaps explained by the fact that the annual demand is so great that growers find it hard to increase their stock rapidly enough to meet it. When the first cost is considered and the usual losses added, it is not surprising that so few are grown to name.

South Lancaster, Mass.

E. O. Orpet.

Covering Greenhouse Walls.

A BLANK wall, such as is often seen in small conservatories, especially those attached to dwellings, detracts greatly from the appearance of the house. Such a wall may be covered in various ways, and one very pretty way is by a screen of earth attached to the wall in which are planted a variety of small plants. Probably the easiest and best plan for such planting is to put strong screw-eyes into the wall at short distances apart, using eyes large enough to project three or four inches from the wall, and to these to fasten strong galvanized wire netting with meshes measuring from three to four inches. The space so formed should then be filled in with a coarse, open compost, in which the plants may be set through the meshes of the netting. A charming effect can thus be secured by a proper mixture of plants with bright foliage and Ferns. Among the former are Marantas, small Crotons, Anthuriums, Peperomias, *Isolepis gracilis*, *Hoffmannia refulgens*, small *Dracænas* and many others, while the list of Ferns may be an extended one. The *Adiantums* will naturally take a prominent place, such sorts as *A. cuneatum*, *A. hispidulum*, *A. capillus veneris* and *A. assimile* being almost indispensable, while some of the *Nephrolepis*, *Pteris serrulata* and *P. cretica*, in their various forms, are almost equally useful. If the wall to be covered is in a Fern-house, the covering may consist entirely of Ferns and Lycopods, without any admixture of other foliage-plants. Among the Lycopods, *Selaginella Wildenovii* is especially handsome for such use, the bluish tint of its fronds being remarkably attractive, but as the shoots of this species will sometimes attain a length of six or seven feet it becomes necessary to peg them into the soil in order to keep them from falling down. *S. uncinata* is also an admirable sort, and will cling closely to the soil without any special attention. *S. Martensii* and its variegated form are also useful plants for this purpose. Among Ferns the *Davallias*, and some of the *Polypodiums* and *Aspleniums*, should not be neglected. Little need be said as to cultivation, for unless the soil on the wall be overwatered before the plants become established, there will be but little difficulty in securing a healthy growth of the Ferns and other plants recommended.

Where the use of this plan would be inconvenient or impracticable, the wall may be readily covered with *Ficus stipulata* or *Pothos argyræa*, or other close-growing creepers, these two being decidedly among the best for the purpose, from the fact that their rootlets cling as firmly as those of the Virginia Creeper, and their foliage is neat. But whatever plants are used for this purpose they should be entirely free from scale, mealy bug or other insects, as it is practically impossible to clean them afterward, and when once infected with such vermin plants soon become disfigured or entirely ruined.

Holmesburg, Pa.

W. H. Taplin.

Two Good Climbers.

DURING the winter months no plants are more attractive than *Bignonia venusta* on account of its abundant flowers and their bright color. The flowers are tubular, three inches in length, with five oblong lobes, and a very bright orange color. They are produced in terminal axillary clusters in great profusion. A well-grown plant on the roof of a conservatory will have pendent sprays from two to five feet long, bearing hundreds of flower-clusters. The *Bignonia*, to attain such luxuriance, requires a good border to grow in, but it will also succeed well in a box three feet square and nine inches deep. Perfect drainage is necessary whether the plant is in box or border. Good turfy loam, with an admixture of one-third leaf-soil, or well-decomposed manure, makes a suitable soil, and if the loam is heavy sand may be added to keep it porous. Watering must be liberal during the growing season, with occasional liquid manure, and the foliage must be kept clean and healthy by syringing. The plant enjoys full light and an ordinary greenhouse temperature, requiring little shade in summer, as the matured wood produces more and better flowers than soft unripened wood. It continues in bloom for several weeks during the winter months. After flowering, all weak growths and branches that have produced flowers should be cut away, and new growth should be encouraged for next winter's flowers. The young shoots should be trained and tied to wires or rafters, as the tendrils, if not attended to, will soon form a tangled mass. This *Bignonia* is easily propagated by ordinary methods from young stiff side shoots in spring.

Lophospermum (*Maurandya*) *scandens* is a most graceful plant, and adapted to many modes of culture. As a winter-flowering plant it can be trained to wires under rafters of the

greenhouse or along under the angles of the rafters lengthwise, from which graceful branches will hang, producing freely rich *Gloxinia*-like flowers of a deep rosy tint. It is also adapted for trellis-work, but climbers on such pieces are usually stiff and formal. Most of them are best trained to wires under rafters or along the edges of benches lengthwise of the house. The stronger ones can be trained near the top of the house, others near the angle of the rafters below. The *Lophospermum* thrives well as an ordinary house or window plant in winter. Out-of-doors it is one of the best climbers for summer decoration, and it can be planted against rustic-work fences, poles, trained to wires or strings by the dwelling-house, piazza, or any other place where such plants delight to ramble. For pot-culture the soil should not be too rich. A mixture of good turfy loam and manure that has been laid up a season is useful for most kinds of greenhouse-plants, with an admixture of leaf-soil and sand to keep the soil porous. Good drainage is indispensable with all pot-grown plants. It is easily raised from seeds or cuttings early in the season, for summer use, and in August for winter-flowering.

Dongan Hills, N. Y.

Wm. Tricker.

Veltheimia viridifolia (*Aletris Capensis*) is one of those odd bulbous plants often to be found in private greenhouses, a reminiscence probably of the time when Cape bulbs were more popular than at present. Like most Cape bulbs, it seems to need cool treatment, with very cautious forcing and a perfect rest after flowering. At least, I find that the bloom is made abortive by too much heat. In the cool house bulbs started in the early fall form thick undulated dark green leaves. The flower-scape is smooth, spotted with brown, and about a foot high, and is furnished with numerous flowers in a rounded raceme. Individually these are rosy pink and spotted, and about an inch long, and make the plant, which is not a showy one, interesting in a collection. The bulbs are increased by offsets, or if the leaves are stripped and inserted in earth they are said to produce bulbs at the base.

Saxifraga cuscuteformis.—The Dodder Saxifrage is an interesting Japanese species, but owing to its peculiar cultural wants is not often seen in gardens. In habit it seems allied somewhat to *S. sarmentosa*, but the runners are fine and Dodder-like, whence the name. The plant is low-growing, with ovate leaves, which are beautifully reticulated with white. In the open it flowers in early summer, with abundant but small white flowers. It is not at all hardy, and its principal value is found as an ornament to the cool house, where, if kept free from too much moisture, it grows freely, and shows finer markings than when grown in the border. Outside, during mild weather, it flourishes in the raised border, pushing stolons underground to throw up leaves in unexpected places, but let dry hot weather come the plant quietly disappears; not to be lost, however, for it forms small corms, which are ready to revive under favorable conditions. A plant of this character is apt to exhaust the patience of all but those fond of peculiarly dainty subjects.

Saxifraga Camposii, or *S. Wallacei* of gardens, is a striking contrast to the above-named variety, and is probably one of the best of the smaller Saxifrages. It is hardy if protected from excessive moisture, and is also useful in the cold house. In such a house the flowers are just opening. These are white, not quite an inch in diameter, and very freely produced on stems three to six inches long. The foliage is flabellate, deeply cleft and toothed.

The Forest.

Forestry for the Farmer.

A FEW weeks ago Mr. Gifford Pinchot read a paper on the above subject before the "New York Farmers," and we give below an abstract of it.

The term forestry has come to be associated in the United States very largely with the climatic influence of forests, and the much more important matter of forest-management has been almost wholly overlooked. This is unfortunate. Forest-management we can speak of in definite terms, but our knowledge of the influence of forests on climate is vague and incomplete. Moreover, much that has been said about it is palpable exaggeration. The whole question lacks the immediate interest to make it thoroughly practical. It cannot be expected that the average farmer will stint himself for fire-wood or refrain from increasing his winter supplies because of the climatic influence of the trees in his wood-lot. The climate

of the future stands small chance with him against the bitter climate of to-day. If this is all that forestry means to the farmer, it may as well stand aside. Tree-planting, except for ornament and protection against sun and wind, is likewise of little interest to him at present. Hitherto the men who have planted trees for profit have been those who could afford to lose their investment. The value of their most useful example will be better appreciated hereafter, but for the present it has little interest to the farmer whose small capital must be made to bring him immediate return. Planting is too costly in most cases, and the returns too distant and uncertain for the man of small means.

But if forestry can help the farmer to grow more railroad-ties and more cord-wood on his wood-lot, if it will increase instead of cutting down the return from the poorer land on his farm, it may be worth his attention. From its very nature this is just what forestry will do. Trees, which are a crop just as much as corn or wheat, will yield an abundant harvest just in proportion to the intelligent care they receive. And the care which woodlands of this kind need is neither minute nor costly. It is all given with the axe, and its quality depends mainly on the choice of the trees which are to fall. It is a difficult matter to formulate general rules for the care of a crop which may contain twenty or thirty different kinds of trees, each with its own requirements as to soil, moisture, light and shade. We are even ignorant, in very many cases, of just what these requirements are. There are certain fundamental principles, however, which the farmer ought to know, which he can easily apply, and which will improve his wood-lot if he does so. He should know, for instance, that the layer of vegetable mold which accumulates under a crop of trees is of the greatest importance to the rapid and healthy growth of his timber. He should know that this layer disappears on exposure to the sun and wind, and that consequently it is a good practice to cut clean only on rich land. In general it is better to take a tree here and there as it becomes ripe, or as it crowds too closely on more valuable specimens. He should apply this principle to the borders of his lot, and leave a dense fringe of low-branching trees and bushes along the edge of the cleared land.

There is a way of cutting over sprout-lands which will give the best results. The important points are to cut near the ground and not to tear the bark loose from the stump. There is a time for cutting which is better than others. There are ways of favoring the better kinds of trees so as to increase their proportion in the mixture. There are ways of cutting off Pine so that Pine will follow it, and not Chestnut or Oak. There are known reasons why certain species follow others after a clear cutting, and why others follow fires. These reasons may vary in each case and for each locality, but there are certain broad facts of the temperament of the different species which always lie at their base.

These are a few of the applications of forestry to the needs of the farmer. I have been indefinite in stating them, and I do not hesitate to admit that we cannot in all cases be precise. Forestry in the United States is so recent that we are far from being thoroughly acquainted with the silvicultural characters of our trees. The general principles of forestry, which are valid all the world over, have come to us from European experience, but the American details remain to be worked out. We know in general that certain trees require more shade in the forest during early youth than others, but we cannot enter fully into scientific detail. We have no systematic knowledge of the requirements and adaptations of our forest-flora in respect to soil, moisture and temperature, as to comparative value for sprout-lands, the age of cutting which will give the best results, and a mass of similar questions. But far more important than all this, the knowledge of how to set about forest-management is wholly lacking among American farmers. Nothing could be more natural, since there exists no good American example.

Forestry, then, offers the farmer certain definite advantages over his present methods of handling his wood-lot, and holds out still further benefits as the reward of wider knowledge. The farmer himself will necessarily have little to do with collecting and discussing the facts which are to yield this wider knowledge, for the reason, among others, that the object of it all does not appeal to him. He must first know what forest-management is and means, and forest-management can never be widely appreciated without concrete examples. Such an example, on a large scale, is about to be supplied by Mr. George W. Vanderbilt, on his estate at Biltmore, North Carolina.

The estate of Biltmore covers some 7,000 acres lying along and between the French Broad and Swannanoa rivers, at an altitude of about 2,000 feet. From the point of view of pic-

turesque beauty, the situation is an exceptionally fine one; but from the forester's point of view, the land is broken, hilly, and, for the most part, not rich. More than half the estate is under forest, chiefly of deciduous trees. In the past the forest has plainly suffered severely from fire, pasturage and indiscriminate cutting. About a thousand acres of the best land, chiefly along the rivers, are devoted to farming. The rest is at present largely waste land.

Here are conditions not unlike those of the average mountain-farm, at least in kind, and the results of this experiment will be of direct interest to farmers throughout a large part of the country. It is proposed to discover whether Biltmore Forest, far from rich as it is either in soil or trees, can be made to yield a uniform annual revenue for an indefinite number of years. It is hoped that this revenue will constitute a fair rate of interest on the value of the property. These things are to be brought about by introducing a rational system of forest-management, which will attempt to harvest each year so much as may be safely cut, but only so much, and under which the productive power of the forest will steadily increase. The forest will be looked upon as a great working capital whose function it is to produce interest, and which does not need to be destroyed in the process. This is, I believe, the only basis upon which forestry will ever become practically accepted among the masses of the people, and for this reason the experiment at Biltmore may perhaps not unfairly be regarded as one of the most important advances that forestry has yet made in this country.

It is too early to speak of the details of the management by means of which it is expected to accomplish these results. The detailed preliminary study of the forest, which must precede any complete plan of action, has not yet been made. It may be said, however, that the management will be based on European models, not adopted, but adapted to American needs. There will be several units of management, and probably as many distinct methods of treatment, both in obedience to the requirements of the forest and because the scope and value of the experiment will be so much the greater. Each unit will be subdivided into blocks or compartments, which will be surveyed and demarcated on the ground. These provisions, as well as many others, will be gathered together in a document called a Working Plan, which will forecast the succession of cuttings for perhaps a hundred years (or whatever the average age of the merchantable log may be found to be), and will prescribe it for five or ten. At the end of this shorter period a complete revision of the working plan will rectify mistakes and readjust the details of the management.

The attempt to do this new thing under the conditions I have described will result, it is hoped, in much knowledge of value to the farmer. First of all, it will draw his attention to the fact that there is such a thing in America as forest-management, and that will be a point gained. Then it will show him, if he chooses to learn, what forest-management means and how it is applied, for it is intended to make a fully illustrated exhibit of the Biltmore working plan at Chicago. But it will not appeal only to the farmer. As the first attempt of its kind in the United States, the experiment at Biltmore will have, it is hoped, a distinct national bearing and importance. It should do much to remove forestry from the anomalous and often illogical position into which the mistaken zeal of some of its friends has forced it, and to ground its roots in the solid earth of business common sense. Not only does it enter a new field, but it asserts a proposition which must ultimately lie at the base of forest-preservation in this country—namely, that it is not necessary to destroy a forest in order to make it pay.

New York.

Gifford Pinchot.

Correspondence.

A Japanese Flower Party.

To the Editor of GARDEN AND FOREST :

Sir,—In reading Mr. Conder's book on Japanese floral arrangements, recently so instructively reviewed in your columns, I was particularly pleased with the account he gives of the entertainments, at which, for the edification of the guests, the principal feature is the preparation by a member of the party of one of their fanciful bouquets, if indeed it is permissible to apply our occidental term to anything so poetical and conventional, as the graceful but singular grouping of a few twigs and flowers, which the Japanese admire.

This Oriental has brought "good form" down to the nicest point; indeed, to such an extent has he carried it that he is not even permitted to apply the wrong adjective to a flower, so

that one may imagine what dismay such a ceremony would create in the mind of a traveling Englishman accustomed to render his impressions by a few words-of-all-work. To find reasonable and appropriate equivalents applicable to flowers for his easy-going vocabulary of "jolly," "beastly," or "awfully," must tax the Briton's dictionary and his interpreter tremendously; for the Japanese, who admits no flower out of season, regulates his epithets to the occasion with equal precision, and the etiquette of his observations is as carefully regulated by the canon, as that of his performance of all ceremonial obligations.

When the flower party takes place, either by itself alone, or succeeding a banquet, the guests assemble in a room, where, in the alcove with a raised floor, devoted in all Japanese houses to the decorative features of the apartment, there may perhaps be seen a kakemono, or scroll, containing a picture or a poem hanging suspended to the wall. On a low stand there is a dainty tray, upon which are laid a few flowers or branches of Pine, Plum, Bamboo or Cherry; beside them are a pot of water, a pair of scissors, a little saw and a folded napkin, the shape and size and folds of which are also subjected to rules. To these are added the bits of wood or metal by which the stems are held in their proper place, or possibly a bronze crab or two to serve the same purpose in an ornamental way.

After the guests have been received with proper ceremonies and compliments, the host proceeds to roll up his picture or poem, lest the guest should be hampered by having to adapt his arrangement to its subject. Should the guest so desire, he may politely request the master of the house to leave it unrolled, in which case he will compose his monograph on that theme, adapting a Bamboo to a tiger, a Lotus to a stork, or a Chrysanthemum to a flight of butterflies, if that is the proper thing, or some other recondite allusion to the painting, only to be understood of those trained in this polite accomplishment. On whatever basis he proceeds, it is decidedly out of the ruling for the guest to ask for anything that has not been supplied. When the host produces the vase in which the arrangement is to be made, the polite visitor, if it is very beautiful, must protest that he can do nothing worthy of so fair a receptacle. Should the host insist, and his manners, I should think, would compel him always to waive this disclaimer, it is the duty of the performer to make his grouping as simple as possible, in order not to divert attention from the beauty of the flower-jar.

When the guest has completed his arrangement, in which he must be most careful to conform to the myriad rules in which he has been educated, he carefully clears up the litter and deposits it, with the napkin and all the tools except the scissors, upon the tray, which is removed by the host, who assists in gathering the debris. The scissors are delicately left, as a hint that the artist requests that anything redundant in his composition may be removed by the critical examiner, who is requested to improve upon the original idea.

The guests in turn inspect the vase and its contents, with refined and well-fitted compliments for each, the phrases being strictly adapted to the character of the article described—a Pine never being flattered with the same remark made to a Bamboo, a Lotus characterized with a word only legitimately applied to a Plum-branch with its snowy blossoms, nor a *Convolvulus* disgraced by the florid adjective that properly befits a Chrysanthemum. After the arrangement has been inspected by all the visitors, the artist must take it to pieces, unless especially requested by the giver of the entertainment to permit the honorable performance to remain intact for the glorification of his humble room. This final ceremony being over, the party breaks up, with more gracious civilities of leave-taking.

In inspecting the curious lines and curves of the branches and blossoms that compose a Japanese flower-grouping, which can never be called a nosegay, since fragrance is eschewed in its selection, the uninitiated wonder how the plants can be retained in the attitudes they are made to assume; but this mystery is solved when, in Mr. Conder's book, we find illustrations of the wires, and split Bamboos, and curiously shaped bits of wood, which really serve to keep them in place. When grouped in baskets, according to a usual Japanese custom, the stems are inserted in tubes of Bamboo filled with water, which serve to keep them fresh. There are also very interesting devices here revealed for preserving the freshness of flowers after they are culled, which may well be studied by our own builders of bouquets, to enhance the durability of the more fragile specimens. Indeed, in this pleasing art, as in more important ones, we may well borrow ideas from our oriental contemporaries, who, in delightful sentiment, in poetic restraint, and in the recognition of the value of simplicity, are the masters of us all.

New York.

Sidney Hyde.

Carnations, New and Old.

To the Editor of GARDEN AND FOREST:

Sir,—With the exception of the Chrysanthemum, no florist's flower has been so much improved as the Carnation. Few occupations are more fascinating than raising seedlings of this popular flower, and, in a commercial way, few ventures of the kind are more likely to be profitable. The result is, that a large number of enterprising and intelligent florists are devoting themselves to the cultivation of this flower, and the number is increasing every year. There is much diversity of opinion as to what constitutes an ideal Chrysanthemum-flower, owing to its wide variation in form, but in the case of the Carnation there is a unanimity of opinion which is striking. This ideal flower, for which all are working, should be at least three inches in diameter, full, globular (not flat), with stiff, long stems; petals well fringed, and powerfully fragrant. Grace Wilder, though not a new variety, comes nearest to this ideal, but lacks size, and is not as fragrant as some varieties.

I spent a profitable afternoon recently at Framingham, Massachusetts, among the raisers of Carnations there. Mr. Wight is well known as the raiser of Hector, probably the best of scarlet Carnations grown. It is a robust grower, giving abundance of large flowers of the brightest scarlet on long stems. There is every reason to believe it came as a seedling from Florence (Fisher).

Mr. Fisher has raised several standard varieties, among them being Anna Webb, the foremost crimson until the appearance of Ferdinand Mangold last year. There is very little difference, in general characteristics, between the two; the newer variety, however, possesses a superior constitution, and is not so liable to produce "dead blooms." Mrs. Fisher, the best white up to date, is also conceded to be the best cropper grown, Silver Spray (Simmonds) ranking next. During winter, and especially in dull weather, it has a tendency to become pink-tinged, but the raiser hopes, by a little cross breeding, to remedy this, and, judging from several promising seedlings on trial, he will succeed. I noted in Mr. Nicholson's greenhouse (also of Framingham) two of Mr. Fisher's seedlings, which he has on trial. They belong to the striped section, and should be extensively grown. Paxton is crimson striped on a white ground; it has a handsome and attractive flower, and is one of the heaviest winter-bloomers. Mary Fisher is the brightest terra cotta I have seen. It is scarlet striped on a yellow ground, suffused with violet. Though not a prolific winter-bloomer, it comes in with great force in spring.

The fame of Grace Wilder, which is generally considered the best pink Carnation, has stimulated much competition, and the rivalry has produced several excellent varieties, including Mrs. Mangold (Mangold), salmon-pink; Helen Galvin (Wight), rose; Tidal Wave (Simmonds); Century (C. T. Starr), and Fred Craighton. The most promising rival I have yet seen is a seedling of Mr. Fisher's, which is in every way a counterpart of Mrs. Fisher except in color, and should it prove as good on further trial as it now promises, it will be sure to take a leading place.

At Mr. Nicholson's I saw one of the finest houses of Carnations I have yet seen. The house is one hundred by twenty feet long, with a south-east aspect and three-quarter span. He plants on solid beds in the centre, and uses benches for the sides. His experience is that benches are somewhat better for winter-cropping, and that Anna Webb, with possibly a few other varieties, does better on benches, the reason being, perhaps, that benches are warmer, drier, and admit of frequent watering. On the contrary, Grace Wilder does better on a solid bed, and this is, perhaps, the secret of Tailby's uniform success with this variety. Mr. Nicholson was kind enough to give me a few dates and figures, which alone will give an idea of the abundance of the crop taken from this house. In September, 1890, 1,700 plants were put in, which number was reduced to 1,400 in February, to make room for other plants, but from that date until September, 1891, 120,000 blooms were cut, mostly with long stems. September, 1891, 1,950 plants were put in, and the average up to date has been 10,000 flowers a month.

Wellesley, Mass.

T. D. Hatfield.

California Horticultural Affairs.

To the Editor of GARDEN AND FOREST:

Sir,—This season I observe a great change in the demand for fruit-trees. Last year it was for Peaches and Apricots, but now Almonds and Prunes lead all the rest, and the nurseries cannot begin to supply the orchard-planters. Looking back over the last twenty years, I can remember many flurries in

the tree market. It is "everything by turns, and nothing long," in California. In 1875 my father burned thousands of Apricots because every one wanted Cherries; a few years later people could not be persuaded to plant Cherries, but they had much faith in Bartlett Pears. Almost every year the demand changed. Almonds have been favorites of planters perhaps three or four seasons in the last twenty years. So many were set in unsuitable soil that the years of heavy planting have added little to the profitable orchard area. The Almond will grow in many places where it will not fruit. The reason why Prunes and Almonds lead this season is probably because the product is so easily marketed. Dried fruit, nuts and raisins cost less freight, and freight is one of the most expensive items in California farming.

Some recent observations upon Fig-trees at the four outlying experiment stations of the State University are soon to be published. They show that the University has fifty-one varieties of Figs growing at the stations, and that a great difference exists among the varieties in point of hardiness. A new variety, Dorée Narbus, withstands with ease eighteen degrees of frost, while the well-known California Black, introduced by the Spanish priests more than a century ago, is badly frozen. As a rule, a temperature of twenty degrees is as low as the Fig can safely endure, but there is a greater range of difference among the leading varieties than in the case of most other deciduous fruits. Fig-growers, to be successful, will have to study tables of climate more carefully than heretofore.

Every year new light is thrown upon the climate of California, as signal service observers increase in number. It has been shown that a difference of a few feet in elevation or a few hundred yards in distance makes a vast difference in the climate. The Coast Range, for instance, though usually spoken of as one great mountain-chain, is really composed of many groups, isolated or linked closely together, all with valleys, high plateaus, river systems, cañons through which fogs and winds may sweep, and sheltered places of semi-tropic warmth. In general, it may be truthfully said that the areas of equable climate are limited; much of the foot-hill country is subject to more sudden changes and greater extremes of heat and cold than is generally shown by the misleading mean-temperature tables which sometimes appear in the newspapers. Land-speculators have sold thousands of acres as frostless, on which no horticultural skill could ever grow the orange, lemon and fig with profit or on a commercial scale. Hardly one-third of the trees of more tender species planted by hopeful land-owners are brought to successful bearing; the rest represent the inevitable waste of ignorance and folly. It is beginning to be understood in California that every orchardist should own a maximum and minimum thermometer, and that some one in every town, village and district should keep careful climatic observations.

The prospects for a satisfactory display at the Chicago Fair are still uncertain. There are hundreds of applicants for positions, but few of them seem to be practical outdoor men with comprehensive ideas of securing and displaying an adequate exhibition. In the line of orchard products the state will probably be well represented, particularly in oranges, olives and other semi-tropic fruits. Unless a better spirit of organization is shown, we shall fail in the scientific assembling and classifying of our products.

On the 27th of January the most noticeable flowers blooming in the garden at Niles, Alameda County, were Camellias, Catalonian Jasmine, Magnolia stellata, Japanese Apricot, Paper White and Chinese Narcissus, Tartarian Honeysuckles, Roman Hyacinths and some late Chrysanthemums. Among Roses the Papa Gontier and Safrano are perhaps the most floriferous at this season. Lamarque and Rosamond are also worth especial mention. There are Violets, Heliotropes, yellow Oxalis, and no end of Geraniums. The Daffodils are blooming, and in a week more the Japan Quince will be in flower; so will the double Cherry, Peach and Almond from Japan.

Niles, Cal.

Charles H. Shinn.

Trees and City Officials.

To the Editor of GARDEN AND FOREST:

Sir,—The ignorance of the average American municipal official as to even the money value of trees was rather strikingly illustrated in Philadelphia some twenty years ago. The Legislature having shown its appreciation of the use of small parks in a city by enacting that one of our few squares should be occupied by the new city hall, and the voters having selected for immolation the largest open space within the old city limits, it became necessary to remove the trees. Bids for the

job, which was required to be done in ten days, were advertised for, and a farmer living near the city tried his luck with the other bidders. He at first thought of offering to buy the trees for \$100, but experience suggested asking \$100 for relieving the city of its superfluous shade. After much entanglement in municipal and political red tape, he obtained the contract, which netted him over \$1,000 by the sale of the wood, in addition to the \$100 agreed upon. This gift of city property, with a ten per cent. bonus into the bargain, seems odd enough, but as the next bidder asked \$4,500 for the same work, the city's loss was at all events not as great as it might have been.

This was, it is true, twenty years ago, but to judge from the annual tree-butchering, miscalled trimming, in our streets, and from the neglected look of the trees in many parts of Fairmount Park, especially the Wissahickon woods, we would seem to have advanced but little as yet in our comprehension of how best to use these gifts of nature either for pleasure or profit.

Recent Publications.

Our Trees. By John Robinson. Published by the Essex Institute, Salem, Massachusetts, 1891.

The articles of which this little book mainly consists were published originally in the *Salem Gazette*. Some additional matter has been introduced, and they are now offered in a neatly printed volume of one hundred and twenty pages. The book is strictly local, and is intended as a popular account of all the trees to be found in the streets and gardens of Salem and of the native trees in Essex County, Massachusetts. Salem seems to be a very good field for such a work as this, for ninety per cent. of all the trees native to New England may be found within the city's limits. The sketch is not confined, however, to native trees alone, for all the more important introduced species that are used in ornamental planting are named and described. The trees are taken up in botanical order and introduced in family groups, and the reader is directed to different parts of the city, or its immediate neighborhood, where examples of each species may be found and observed by any one who may care to do so. We do not remember any other guide-book of this kind, and its value is apparent when we consider that persons with some botanical knowledge, and familiar even with the rarer wild flowers, have often only a slight acquaintance with our trees—that is, they do not know them well enough to distinguish the different Oaks or the different Pines from each other, or to separate the Birches and Hornbeams, or to tell which cultivated trees are imported and which are native. If the young people of Salem, and the older ones for that matter, would take this book for a guide and study the various trees which are pointed out throughout the year, they would become pretty familiar with a great number of species, and they would acquire habits of observation which are a valuable part of mental training. The book contains many historical facts of local interest, besides the descriptions of the trees, and, altogether, the city of Salem is to be congratulated upon the possession of such a manual. It would be a benefaction to many other towns if so competent an observer as Mr. Robinson should give similar accounts of their trees, and if such treasuries of information were common they would help to remove the reproach that there are few American people who know even the names of the trees that grow in the streets through which they walk every day.

Notes.

The sixth annual Orchid show, under the direction of Messrs. Siebrecht & Wadley, will open on Wednesday, March 2d, at the Eden Musée, in this city.

One of the English papers states that some old bulbs of Cyclamen Persicum, kept in a cold Peach-house, were subjected to such a low temperature not long ago that the soil in which the bulbs were growing was frozen quite hard for several nights; and yet this did not seem to injure the plants appreciably.

Miss Mary E. Banning has presented to the State Museum of Natural History at Albany a list of the fleshy fungi of Maryland, which describes 179 species, fourteen of which are stated to be new. The manuscript, accompanied by 175 colored plates, has been bound in a large volume, and will doubtless be of much service to botanists.

At the Experiment Station at Kingston, Rhode Island, where there has been some study made of the disease known as the

Scab of the Potato, it has been found that spraying the seed potatoes, and the soil about them after they are in the furrows, with the Bordeaux mixture checks the development of the disease.

The Peruvian Trumpet Flower, a name which has been applied to *Brugmansia suaveolens*, will not endure frost, but *Meehans' Monthly* invites attention to the fact that it will stand very rough treatment, and this makes it a favorite everywhere for summer decoration. The plant can be taken up in the autumn and preserved in the cellar. The numerous large white trumpet-shaped flowers make it very attractive outside of the particular fragrance which is one of its characteristics.

Certain Japanese writers declare that in placing a floral design in a room care should be taken to contrast its style with that of the adjoining garden, an idea which seems fanciful to us, but is quite reasonable in Japan, where, during most of the year, the paper sides of the house are thrown wide open toward the garden. If the garden, say these writers, consists of an arrangement of lakes and hills, the floral group in the room is best when it has a moorland character; but if the garden be flat and waterless, then mountain-trees and water-plants may be used in the chamber.

Among the foreign plants which have become very troublesome in the Australasian islands the Sweet-brier holds a prominent place. "Introduced as a hedge-plant," says Professor George L. Goodale, "it has run over certain lands like a weed, and disputes every acre of some arable plots. From the facility with which it is propagated, it is almost ineradicable. There is something astonishing in the manner in which it gains and holds the ground." Gorse, Brambles and Thistles also prove much more difficult to eradicate in the southern hemisphere than in the northern, where they originated.

The Colorado Forestry Association has memorialized the President in behalf of a new forest-reservation, the most important one yet asked for, and including the crest of the Rocky Mountains. This range crosses the entire state, and its high interior region contains one hundred and forty peaks exceeding 11,000 feet in height. Vast areas of timber have already been desolated, and yet this is one of the chief distributing centres of the continental water-system containing the sources of the North Platte, the South Platte, the Arkansas, the Rio Grande, the Dolores, the Gunnison, the Grand, the White, the Yampa, streams which are not only important to Colorado, but to the neighboring states and territories. The petition designates for the proposed forest-reserve all public lands along the crest of the mountain-ranges and spurs of the state, and upon each side thereof for a distance of six miles, more or less, according to the width of the timber-belts in different localities.

At the late meeting of the Carnation Society Mr. Lonsdale exhibited some buds of Carnations with specimens of a kind of worm which had worked upon them before the flowers were expanded. In some cases the base of the calyx was eaten through. In other places the petals had been eaten where they had commenced to unfold. In most cases the objective point seemed to be the nectar at the base of the flower, although the petals also seem to have been devoured. Professor Riley identified the marauders as variegated cut worms (*Agrotis saucia*), and he suggested that they might have been brought into the greenhouse with the earth from some sod-land. He advised the spraying of the plants with Paris green at the rate of one-quarter of a pound to fifty gallons of water, and a thorough wetting of the soil with dilute kerosene-soap emulsion. According to a report in the *American Florist* the remedy was tested at once, and seems to have been effective.

The plant known variously as the Husk Tomato, the Strawberry Tomato, the Ground Cherry and the Dwarf Cape Gooseberry is a species of *Physalis* (*P. pubescens*), which has been cultivated for years and is well worth growing in the home garden. Professor Bailey has been making some experiments with this and other species of *Physalis*, of which he gives an account in a late bulletin. He has tested seven species, but only three of them have been cultivated as fruit-bearing plants. The chief objection to the one named above is its prostrate habit, which causes it to spread over too much ground. Professor Bailey has been unable to hybridize it with others. The species *P. Peruviana*, or the true Cape Gooseberry, is too late for our climate. It has been in cultivation for two centuries, and is a valuable food-plant in the Cape of Good Hope and New South Wales, where it is eaten in a variety of ways. The Pepper-leaved *Physalis* (*P. capsicifolia*), erroneously called *P. edulis*, is unfit for general cultivation for

fruit, although it is an interesting plant for the botanical student.

A recent bulletin from the Mississippi Experiment Station gives an account of the southern Tomato-blight, which was studied there a year ago by Dr. Halstead, and which had become so destructive as to cause alarm among the growers of that region. The blight is due to a bacterial germ. Plants first wilt, then lose their color and die. This blight seems to be identical with a bacterial disease of the Potato, and it can be communicated from one kind of plant to the other. The same seems to be true of a blight of Melons and other cucurbitaceous plants which prevails in the same region. If this is true, it is plain that the soil may become contaminated with bacteria from any one of these three crops, so as to make it unfit for either of the other two. The blight can be more readily disseminated by the Potato, since it is propagated by tubers, which may carry the germs. All the diseased plants and litter should be burned at harvest-time. Repetitions of either of the three crops on the same field should be avoided, and spraying with the Bordeaux mixture is recommended where fear of the blight is entertained. This treatment has proved efficacious in the case of the Potato.

A few months ago we quoted from the *Bulletin of the Torrey Botanical Club* an account of a Linden which had taken root in the decomposed wood of its own trunk. Mr. G. B. Sudworth, of the Forestry Division, of the Department of Agriculture, now reports in the same journal that he has observed a similar phenomenon in a small White Mulberry which stands in the grounds of the Department. The tree, he says, has been more seriously injured than was described to be the case with the Linden, "a considerable portion of its trunk being destroyed by decay. The adventitious roots spring from the free border of a longitudinal crack where the trunk forks, the edges of the wound having been 'healed' for some time, while the subsequent decomposition of the exposed inner layers of wood formed a quantity of mold, which, lying in contact with the healed borders, seems to have induced the growth of adventitious roots from one side into the decayed mass. In considering the precise conditions under which this apparently peculiar growth is produced," adds Mr. Sudworth, "as well as the fact that, as far as observed, the adventitious roots proceed only from vigorous, newly formed wood, perhaps these cases may not be more phenomenal than the production of roots from a cutting or from a layered branch, where new wood is subjected to the same conditions, and therefore seem to be quite analogous to the case in which the Linden and Mulberry produced roots, if not an expression of the same law. The apparent incongruity exhibited by a plant deriving, as it seems, nourishment from its own body appears more striking at first thought than if we consider that the lignified part of any living trunk, if reduced by decay, is as fittingly a plant-food as that which may be appropriated by the same individual from its own accumulation of decayed leaves, provided, of course, the necessary moisture is present in the humus."

The Proposed Speed-road in Central Park.

WE sometimes feel like offering an apology to our readers for restating so frequently some of the fundamental principles which should control the design, the development and the management of our city parks if they are to attain their highest possible value. But we are too often reminded that there are many people of intelligence and refinement who seem to have no adequate appreciation of the elementary truths upon which all thought and action in park matters ought to rest. Just now certain wealthy gentlemen of this city have revived the project to run a broad, straight and perfectly level road through Central Park along its western boundary line, to be used exclusively for driving horses at speed; and either they do not understand that this will mean the utter ruin of the park as a place of rural recreation, or, if they do understand this, they consider the use to which they propose to devote it a more important one than that for which it was originally intended.

The primary purpose of the park was clearly discerned when the land was bought. The projectors of the park realized that the growing city was rapidly obliterating every trace of natural scenery from Manhattan Island, and they deemed it a wise and wholesome provision to save a central area where trees and grass and flowers—a picture of pastoral peace—should be preserved as a refreshing antithesis to the rigid lines of stony streets and buildings about it. The city gave bonds to hold it in trust for posterity, and for this single use. It was planned, graded and planted to this end alone. Every road and path and archway was constructed solely to afford the best opportunity for enjoying the beauty, melody and fragrance of a natural landscape. All intelligent men who have given profound thought to this subject are unanimous in their judgment that this was a worthy purpose; that the city did wisely in expending millions of dollars to secure a park designed with such a motive; that, indeed, no city of any pretension, and New York least of all, hemmed in as it is by waters, which

forbid its expansion except to the northward, can afford to be without such a park. And yet these eminent citizens are asking the Legislature to authorize the desolation of a portion of this work, and to insure the final destruction of all of it after millions of dollars and the thought and labor of years have been expended in developing its capabilities. It is even said that one of the Park Commissioners has lent his influence to the movement, although his position is that of a trustee appointed to protect from all such assaults the public property which he seems willing to surrender to its enemies. A Park Commissioner, even if he were empowered to do so by special law, has no more moral right to give over a portion of the park to a use which is not only foreign to its purpose, but utterly destructive of that purpose, than he would have to sell it for building lots.

The promoters of the speed-track urge that paths have been made in the park for visitors to walk in, a bridle-pad for those who ride, carriage-roads for those who drive, and why not, therefore, a special place for those who wish to speed trotters? The obvious answer to this is, that the roads and paths were made not primarily as places for walking or for driving, but in order to enable persons on foot, on horseback or in carriages to enjoy the park itself. That is, the roads and paths exist solely in the interest of the park. The aim of the project in question is just the reverse of this. It is not the construction of another road to open new views or give additional facilities for visiting any portion of the park. It means the destruction of the park in the interest of a road to be used for its own sake by the few people who wish to drive at speed. The principle is utterly vicious. Even if it is the duty of the city to provide a track for the owners of fast horses it does not follow that the park should be sacrificed for it. If the city needs a track for running horses—and if a track for fast driving is provided why not for hard riding and hurdle-jumping—or a military parade-ground, or a field for baseball, football and other athletic sports, the obvious course is to buy the ground and prepare it for these purposes. It would be the work of barbarians to confiscate Central Park for any one or all of these uses, or for any other foreign use, after it has become famous as the most beautiful, and, therefore, the most useful urban park in the world, and the object of our noblest civic pride.

We have become so accustomed to apply the name of park to a ball-field, a race-track, a game-preserve, an arboretum, a forest, a country fair-ground, or any other place that is not roofed over, that the popular notion of the meaning of the word has grown confused, if it ever was distinct. Even intelligent people have to be reminded that many worthy purposes to which open-air resorts can be put would be utterly destructive of the value of a park for rural recreation—that is, the value of a park as a park. It is true that opportunity is offered in Central Park for skating, for lawn-tennis and for some other sports, but these have always been subordinate features—mere incidents which have not been in conflict with the controlling purpose of the work. How far such incidents can be safely multiplied is a matter of judgment; they certainly have never yet been obtrusive or disturbing. Such games are not in themselves inconsistent with the refreshing influence of quiet scenery. No portion of the park has been turned into a desert to make room for them; no grass has been replaced by gravel, nor has any wide swath a mile long been mowed through the trees for them. Every year since the park was designed some class or interest or movement has made an effort to condemn a portion of it to special use; but in the main these assaults have been repelled, and when the power and persistence of this pressure is considered, the salvation of the park—that is, its preservation for its original purpose in ever-growing beauty and value—is something of a marvel.

We have discussed this matter in a general way, presenting only elementary principles which ought to protect a park from invasion of any disturbing character. Perhaps it should be said that this speed-road project is the most

dangerous attack with which the park has been threatened. The most important plantation in it is the tree-border, which, so far as possible, shuts the city out of sight. This project would practically sacrifice the entire border of one side of the park, or it would narrow into pettiness the meadows whose breadth gives the park its essential charm. It would warn out as with a line of fire all visitors from the west side, unless they reached the park through tunnels under the road or by bridges thrown across it. It would make an offensive exhibition of the power of money to confiscate for the pleasure of a few rich men the ground which offers to the poor of the city their only opportunity to enjoy the sight of verdant fields. No one would think of selecting such a site for a speed-road unless he could steal the land. And when the enormous cost of construction through these rugged rocks and ridges is added to the greater loss by destruction which the people of the city would suffer, this would prove the most expensive road in the world. And, after all, it would make only a second-class track, which would be abandoned as a public nuisance within five years after it had been finished.

WHAT is the value of a tree? is a question which has lately been settled in the London courts, as reported in a recent issue of the *Gardeners' Chronicle*. It appears that a resident in the suburbs of London had in his garden two Poplar-trees, which protected him from the smoke and noise of trains passing over the rails of the London and North-western Railway Company, whose location his land joined. The trees, for some reason or other, interfered with the traffic of the railroad; the owner was willing to shorten the branches, but objected to cutting down the trees. And then, negotiations for their removal having failed, the company sent its own men and cut them down. They offered to pay two hundred and fifty dollars for this high-handed act, and later increased the amount to five hundred dollars. The court placed the value of the trees at fifteen hundred dollars, and awarded additional damages of one thousand dollars for the injury caused by their removal. An occasional decision of this character in this country would have a very salutary influence upon telephone and telegraph companies, who have come to look upon our highway trees as of no value whatever when they interfere in any way, directly or indirectly, with their business.

Bright Winter Leaves.

EVEN in our colder northern states nature has some bright color for winter's relief. Against the background of her sombre browns, purplish grays and evergreens gleam out, now and then, scarlet winter fruits and berries, and the shining crimson stems of vigorous young tree-shoots. Traveling southward one finds, interspersed among the open woods, clumps of Holly (*Ilex opaca*) all aglow with clusters of bright berries thickly set among its thorny shield-like leaves, and in the tops of Oak and Gum trees are brilliant green circles of Mistletoe, gemmed with pearl-like berries.

These glints of color, on a level range of vision, the eye quickly takes in, but close down to the forest-leaves at one's feet, the persistent foliage of a number of forest-plants form patches of glowing color quite as cheering to look upon.

Tiarella cordifolia, our dainty little Foam Flower, retains its large, Maple-shaped leaves all winter here in the middle Alleghanies. These leaves all spring in a great tuft from the root, and, ripening into glowing patches of yellow and scarlet, gleam out brightly from rocky eastern hill-sides. I have seen these leaves, still soft and pliant and vivid in color, late in spring, with the delicate sprays of the plant's white flowers above them, before the young season's leaves were sent upward.

Often in the open woods in winter you come upon great beds of *Galax aphyllia* leaves. They are of all colors, from the soft green of their summer hue, shading up through tints of golden green and scarlet and crimson to darkest brown-maroon. These quaintly shaped round-cordate leaves, with their crenate-ruffled edges, are borne upon slender wiry stems six or seven inches high. Their texture is stiff and glossy, and they shine as if varnished, and rustle softly as the wind

sweeps over them. In the sunlight they gleam like a beautiful mosaic.

The leaves of *Asarum Virginicum* are as handsome as those of any *Cyclamen*, and, when bruised, exhale a strange, delightful odor. On exposed, bare hill-sides the cold gives to the thick, leathery leaf a metallic purple lustre, but usually it is bright green mottled with white, like the *Cyclamen*-leaf, which it also resembles in shape and size. A curious little family of pitcher-shaped blossoms may be found clustering close to the earth beneath these leaves in March and February.

A darker leaf, but one quite as beautiful and persistent throughout the winter, is that of the Dye Bush. Its common name was given with reference to the yellow dye extracted from it I am told. But its winter-leaves are a soft, rich purple color, as smooth and pliable as velvet. I have seen the mountaineers bind them upon wounds for healing as they would a salve. The shrub grows only three or four feet tall, and its mantle of purple leaves covers it thickly.

Western North Carolina.

L. Greenlee.

Winter Rambles in the Pine-barrens.—III.

ALLIED to the Alder and Paper Birch, and the only representative of the Sweet-gale family here, is a petty shrub, *Myrica asplenifolia*, or Sweet Fern, found sometimes in the sterile soil. It corresponds in size to the Low Birch (*Betula pumila*), likewise found in neighboring bogs. It is also much like it in color, the bark of the stems being brown, and that of the branches reddish brown. It is a stout little shrub, two or three feet high, with long branches ascending or horizontal, making it tree-like in shape. Its chief attraction now is the prominent, club-shaped tufts of male catkins at the ends of the long branches. They are in clusters of five or six, closely appressed to the branches, often slightly twisted so as to form an imperfect spiral around the branch, and point away from the plant like an outstretched finger. The pointed scales are softly hairy, and, like the ends of the branches, are sprinkled with resinous dots, which shine like flakes of pyrite under a lens, the whole arrangement offering a singular blending of color coming from the brown scales, gray hairs and golden dots. The aments and young branches exhale the same resinous odor that the leaves do in summer, though not as strong, from which agreeable property, and the fern-like appearance of its pinnatifid leaves, it obtains its popular name, Sweet Fern. It is regarded as one of the most characteristic species of the Pine-barren flora, but I do not find it as abundant among the Pines here as it is farther north. In fact, it is more common in the sandy region bordering the Pine-belt than in the Pine-belt proper.

There is an interesting moss-like plant on the sand-hills belonging to the Club Moss family, the little *Selaginella* (*S. rupestris*). It grows in close tufts, rooting in the sand as effectually as it does to the rocks, which are its more common home, and have given it its name. The short, roundish stems, densely clothed with small grayish green leaves, are rigid, and often nearly buried in sand, for the plant delights in exposed positions, not on shifting dunes, but on hills partly overgrown with trees, when it helps to keep the sands in place. It is very different in color and appearance from the flat-stemmed *Selaginellas*, common in cultivation for the decoration of flower-baskets and the edges of flower-pots, one of which, *S. apus*, is found sparingly in the wet sands of this locality.

Two of the true Club Mosses, with evergreen foliage, grow in the Barrens, but are not common. One is the Ground Pine (*Lycopodium obscurum*, var. *dendroideum*), seen in rather moist, shaded ground, with upright shoots half a foot high and closely resembling a miniature tree rising from a creeping subterranean stem. They are always bright and glossy, with thick, lance-linear, incurved leaves closely attached in several ranks to the stems and spreading branches. The erect, club-shaped spikes of fruit, dry and faded, may be seen adhering to the summit of the stems. The other is *L. clavatum*, also known as Ground Pine, but with less of the appearance of a tree, smaller and less striking. The branches are flat and forking and spread like a fan, and are provided with minute awl-shaped leaves. The stems creep extensively, sometimes just beneath the surface of the ground, but more often under a covering of leaves or humus. From these several upright stems, three or four inches high, spring up. The fan-shaped branches may start from these stems in such a way as to assume a spiral or corkscrew appearance as they spread. It is a paler plant than the preceding, lacking its glossiness, but excels it in prettiness when in fruit, with two to four cylindrical spikes borne in an upright cluster at the top of a slender

peduncle. While one resembles the Juniper, but with leaves spreading and incurved, the other has the spray of the *Arbovitæ*.

Another plant of the dry sand-hills will lead one to stop and inspect it when met with in the winter. It is the smallest shrub of the flora of the lake, *Hudsonia tomentosa*. The stem rises but little above the surface of the ground, the whole plant being scarcely more than six or eight inches high, its stem usually bending to one side. It branches so excessively as to have a tuft-like crown. The bark is very dark, almost black, and the branches near their ends and all the twigs are covered with a gray tomentum. When seen in the winter, the plant seems dead and uninviting, the slender twigs so brash as to break square off as if dry, thus adding to the deception. But under a thick covering of hairy scales are the small green buds, and the wood of the fresh fracture shows a green color when closely examined. These tiny shrubs make their home in exposed positions where little else grows, striking their roots firmly in the sand, and the apparently dead tufts, at which the wind tugs hard to draw them from the ground, will be lively in the spring, or early summer, with small but numerous yellow flowers.

Englewood, Chicago, Ill.

E. J. Hill.

Pinus latifolia.

DURING last autumn Mr. S. D. Dill, of the Museum of Natural History of New York, has been collecting sections of western trees in order to complete the well-known Jesup collection of woods, which forms so interesting and instructive a part of the exhibit of that institution, and I had the pleasure of accompanying him on one of his last trips, which was to the Santa Rita Mountains of Arizona, for a log of the little-known *Pinus latifolia*.

This tree was discovered in the Santa Rita Mountains by Dr. Heinrich Mayr in the year 1887, and was described from his notes in this journal (vol. ii., p. 496). In searching for the locality we went first to the town of Crittenden by rail, and thence twenty-five miles to the end of a wagon-road that follows a cañon well into the Santa Rita Mountains. This road formerly extended a mile or more farther up the cañon, but the waters of some rainy seasons have washed out the upper part, rendering it impassable for wagons; nevertheless, we were able to drive to some of the trees we were looking for. At this elevation they are to be found only in shaded cañons; higher up the mountain they are sparsely scattered over all the slopes from near, but not on, their summits, downward a thousand feet or more.

In general appearance this tree closely resembles *P. ponderosa*. It has a similar fissured, reddish bark like that, of variable tone, sometimes lighter, sometimes quite dark; the branches described as tortuous are as often not so, and the cones vary in size and shape. The leaves, variable in length, are generally in threes, although sheaths containing two or four can be found. When they are two, the faces are flat; when three or four, they are at first triangular, becoming gradually flattened, with a distinct midrib. The sheaths of the young leaves are more than an inch long, and decrease in length as they increase in age. The trees had borne no cones for two or three years, but under some of them an abundance of old ones were found. They are always more or less oblique at base, and, with age, seem to fall to pieces from that end, showing at first a stipe-like axis. An extreme form of cone, observed only under a single tree, was very different in appearance from the others. They were slightly unsymmetrical, and the basal scales being detached, the remainder were strongly reflexed, giving to the cones a curiously strong resemblance to the head of an artichoke (*Cynara Scolymus*). Our visit being late in the year (November), after an extremely dry season, when all the leaves of the deciduous bushes and trees had fallen, a great portion of the accompanying vegetation was not specifically recognizable.

Some few plants of *Tagetes* and *Zauschneria* were yet in bloom, and their presence, where at the same time the year before there had been snow, was due to the unusually warm November, so warm that a rattlesnake and a tarantula were seen out in the sunshine. This part of the Santa Rita range was very dry, and water for drinking was found at only one place, and there in small quantity. The mountain is covered with bushes, and in some places there are many trees, especially near the summits and about the shaded slopes. The Oak, represented by five species, is very common, and scattered around are *Garrya*, *Arctostaphylos*, *Fraxinus* and *Ceanothus*, growing among Junipers, Madroñas, Douglas Spruces and several species of Pine.

Seed-raising in Germany.

MR. GEORGE F. DANIELS, who has spent some years in one of the chief seed-growing centres of Germany, delivered an address last month before the East Anglian Horticultural Club at Norwich. The *Journal of Horticulture* contains a full report of the paper, and from it we make the following extracts:

It is only within the past twenty to thirty years that this trade has assumed its present gigantic proportions. The increased demand for flowers in England has given a corresponding impetus to seed-growing abroad, where they have the advantage of cheap labor and a climate especially adapted to this work. England, next to America, is the largest importer of German-grown flower-seeds. Besides this, large quantities find their way to all parts of the world. The secret of this successful cultivation lies in the bright dry autumn, which enables seeds to stand longer and become thoroughly ripened. Not only is the climate well adapted for the production and ripening of seeds, but the soil, which in Erfurt is a deep, rich and moderately stiff loam, is all that can be desired for the purpose.

Stocks form one of the leading features in a seed-growing establishment, and are one of the most expensive crops to grow, so far as labor is concerned. They are nearly all grown in pots, only the inferior sorts being left to take their chance in the open ground. One firm grows 300,000 pots of these annually. The plants are kept on stages, like an ordinary greenhouse-stage, and the houses have a wooden or tiled roof to keep off the heavy rain and the too direct rays of the sun, the sides and back being left open. The soil used must be well decomposed or "matured," and free from any vegetable matter. Therefore, three years' supply is always kept on hand, and turned, from time to time, to make it sweet. The plants, which are raised in pits on a slight hot-bed, are pricked into six-inch pots, when in the fourth leaf, seven to nine in a pot, so as to throw up single stems only. There are two reasons for this crowding. Seed is only obtained from the single flowers. As soon as the double ones make their appearance the plants are cut off, thus giving more room for those remaining. Placing several in each pot tends to starve the plants somewhat; and when thus treated they produce a larger percentage of double-flowering plants; this has been proved. Seed saved from plants grown in the open ground does not produce anything like the same percentage of double flowers; fifty per cent. is considered a good average, although in some places it ranges as high as sixty-five per cent.

Stocks require a copious supply of water throughout the growing period, which extends from April to October, except for a week or two when they first show their bloom, when it must be sparingly given, as overwatering at this time would cause them to damp off and encourage the attack of insect pests, which are very troublesome at this period. The labor required in constantly watering and tending such an immense number of pots is very great, and keeps up the price of these beautiful annuals.

Autumn Stocks and Wall-flowers require much the same treatment, but in their case a much longer period is required for growing and ripening the seed. The seed is sown in July, and the plants potted in the same way and kept through the winter, a very difficult thing where proper accommodation does not exist, and the thermometer is often several degrees below zero. The larger growers, who have the room, keep them in cool houses; but in small establishments where such is not obtainable, they are kept in pits well covered with litter, air being admitted on fine days. If the winter proves severe, the plants suffer accordingly, as the pits become snowed and frozen for weeks together, and want of air causes many to damp off.

China Asters form another important feature, perhaps even a greater one than Stocks, and are grown by acres, one firm alone devoting over one hundred acres to them. They are raised in pits and afterward planted out on the beds, where it is intended to grow them for seed. The distance they are planted apart varies according to the variety, but is seldom less than a foot each way. The planting is done by gangs of men, much in the same manner as we place our Cabbages, and each plant is carefully watered to settle the soil around it, the water being conveyed to the fields by carts specially constructed for this purpose. When they come into bloom, they must be constantly examined, and all stragglers and "button-eyed" ones removed. The best flowers are selected in March, and the seed of these is kept for stock seed for next year's growing.

Petunias are raised in pits, then potted and placed on stages in the open after the same manner as Stocks. They require

much attention, as each bloom has to be fertilized by hand to insure the setting of seed. The pollen from the double blooms is very difficult to obtain, the flowers being so dense that they have often to be removed from the plant, then placed in wet sand and pulled open so as to allow the sun and the air to ripen the pollen, which is carefully removed and placed on the finest single blooms. The seed saved from these is called double, but it is rarely possible to obtain more than twenty-five to thirty per cent.

Calceolarias are sown in July and August, and after two or three shifts they are finally placed in six-inch pots about the end of January. In May they are arranged upon the stages outside where they are to bloom and seed. They are very shy seeders, and it is only by careful hybridization that a crop can be insured. Every bloom is examined, and the pollen taken from the stamens and placed on the pistil, and as the operation must be performed when the pollen is quite ripe they must be looked through nearly every day to catch each bloom as it comes to maturity.

Carnations are grown on stages, and are usually propagated by layers. A collar or hoop of wood about one and a half or two inches deep is placed round the top of the pot and filled with soil; into this the young shoots are layered, and when sufficiently rooted they are taken off and potted, the hoop and extra soil are then removed, and the mother-plant kept to ripen what seed there may be on it. Seed is very difficult to obtain under any circumstances, and then only in small quantities. The supply is always limited, and there is not much chance of its ever being much cheaper than it now is. In one establishment I visited ten to fifteen thousand pots were kept going for these alone.

The commoner kinds of annuals are grown in quantities. Mignonette and Dianthus are grown by the ton, and a single firm often harvests several hundredweight of Pansy-seed. Pansies require the closest attention, and must be caught at the right time; if not, the pod bursts and the seed is scattered. Some seedsmen grow Everlastings, and reap many acres of them under cultivation. This forms quite a business by itself. They are dried in warehouses specially built for the purpose, and afterward bunched and packed for export.

The pits in which most of the plants are raised are constructed of wood, and are generally not more than nine to eighteen inches high, with the soil cleared out to a depth of about three feet. They are then filled up in the following manner: A layer of rough stalks, then a good layer of fresh manure to within about nine inches of the top, and well trodden down. This is allowed to settle for a day or two, and upon this is placed a layer of fine soil, in which the seedlings are raised.

During summer they are used for growing some of the more tender annuals, such as Cockscombs, Portulacas, etc., so that protection may be given if necessary during cold nights. The soil and manure is removed in the autumn and carefully put away. In this manner it is being utilized while preparing it for future potting operations. They are used in winter for storing Wall-flowers and autumn-sown Stocks, as before mentioned.

The plan of improving stocks of seed is as follows: As soon as the plants are fully in bloom they are carefully examined, and the best and truest as regards color or shapes are singled out by placing a stake next them. When the seed is ripe they are carefully gathered by themselves and kept for stock the following year. This is very necessary in the case of some annuals, which show a great tendency to revert to the wild state, and, at the same time, it improves the stocks from year to year, so that everything is brought as near perfection as possible.

New or Little-known Plants.

Lespedeza bicolor and Lespedeza Sieboldi.

ONE of the most interesting and valuable plants of our comparatively recent introduction is that known in many of our gardens as *Desmodium penduliflorum*, but which, in some places and by a number of writers, has been called *Lespedeza bicolor*, a name apparently belonging to an entirely different plant.

It is unfortunate that neither of these names is correct. It appears that the plant in question, originally described by Miquel in the third volume (p. 47) of the *Annals of the Museum* at Leyden, should be called *L. Sieboldi*, a name generally regarded as a synonym or representing a variety of *L. bicolor*.

*L. bicolor*¹ is a distinctly shrubby species first described in 1840 by the Russian botanist Turczaninow, and first introduced into cultivation by Maximowicz, who, in 1856, sent seed to St. Petersburg from Manchuria, where the plant is indigenous, as it is also in northern China and Japan.

Desmodium penduliflorum was a name given by Professor Oudemans, of Amsterdam, in 1866, to a plant supposed to have come from Japan, and proved by later importation to have been derived from that country.

It was soon widely distributed, on account of its ornamental value; but it was not for some years, or until the name given by Oudemans had become familiar, that this was announced as but another name for *L. bicolor*. The change of name was not generally adopted by nurserymen. Dr. H. Zabel (*Gartenflora*, 1889, p. 239) first called attention to the fact that the plant should be called *L. Sieboldi*, as being distinct from *L. bicolor*. A series of specimens, mostly of *L. bicolor*, from various localities in their native habitats, show that the species are very variable, especially in foliage. While it may be possible, as intimated by Maximowicz, that there are intermediate geographical forms or varieties which connect the two species, they are so distinct when growing side by side that to deny them specific rank must inevitably cause much confusion. In cultivation, *L. Sieboldi* does not prove any more shrubby in southern latitudes than in northern gardens, but it blooms earlier.

Among the published figures and descriptions of these two plants there is naturally some disagreement of identity. The first and best figure of *L. bicolor* is that given by Ruprecht (*Decas Plantarum Amurensium*, 1859, t. 5). The figure in *Gartenflora* (vol. ix., 1860, t. 299), though poor, is probably *L. bicolor*; that in *Flore des Serres* (vol. xxiii., 1869-70, t. 1888-89), as *Desmodium penduliflorum*, is a good representation of *L. Sieboldi*; and so is the excellent figure by Riocreux, opposite p. 211 of the *Revue Horticole* for 1873. What is figured as *L. bicolor* in the *Botanical Magazine*, 1882, t. 6602, unmistakably represents *L. Sieboldi*, although the description appears to have been drawn from *L. bicolor*; and so does figure 133 of vol. xx. (1883) of the *Gardeners' Chronicle*, in which it was published as *Desmodium penduliflorum*, but corrected in the index as *L. bicolor*.

*Lespedeza Sieboldi*² of Miquel is a strong herbaceous, but shrub-like, plant, having numerous stout pithy stems, from three or four to six feet high, which annually die to the ground or crown of the plant, and are replaced by new shoots each season. The stems are more or less ribbed or angled, and covered with a minute grayish pubescence, which is hardly noticeable on the lower portions, but gives them a silvery white appearance near the top.

The leaves are trifoliolate, the terminal leaflet usually being the larger, the leaflets on the lower part of the stem being from one and a half to two inches long, while those on the upper portion and on the branchlets are often reduced to half an inch or less in length. They are smooth above, and are quite densely covered with a minute appressed grayish pubescence beneath, which gives them a silvery aspect. They are usually elliptical-oblong in shape, shortly tapering toward both ends, hardly half as broad as long, and with or without a slender point or mucro at the tip. The petioles are slender, varying from two or three inches with the larger leaves to half an inch or less in length with the smaller. They are more or less covered

D. Japonicum, Hort. ? (not Miquel).

with an extremely minute silky pubescence, and are provided with two slender, long, pointed, awl-shaped stipules at the base. The short petiolules are stouter than the petioles, usually light-colored and densely pubescent.

The large showy cluster of rosy purple flowers which terminates each stem is composed of numerous axillary racemes from two or three to six inches long. The flowers are much larger than those of *L. bicolor*, and average nearly half an inch in length, the wings, standard and keel being of the same general shape, but nearly twice as large. The five-parted calyx is covered with a grayish silky pubescence, and is about one-fourth of an inch long, the narrow slender-pointed lobes being quite twice the length of the shallow tube, at the base of which there are two minute bracteoles. The immature pod is one-seeded, quite densely pubescent, flattish, more or less ovate, from three-eighths to one-half of an inch long, and tipped with a slender tail-like appendage as long or longer than the pod.

Lespedeza bicolor is a single or few-stemmed, well-formed, woody shrub, attaining a height of seven or eight feet or more by rather slow annual growth. The bark of the stem is of a dark brown color, and is covered by numerous raised dots; the young branchlets are distinctly ribbed or angled, are light green or grayish in color, and are very sparsely covered with minute hairs. The outer portion of wood, or the sap-wood, is of a light yellowish color; the interior is brown or purplish brown, and the pith is very small. The wood is brittle, very close-grained and hard. The leaves are trifoliolate, and the leaflets vary in size from an inch and a half or a little more in length on the larger branches to less than half an inch on the flowering branchlets. They are about two-thirds as broad as long, and usually obovate, obcordate, oval or rounded in shape, often tapering somewhat toward the base, but rounding abruptly at the apex, or commonly truncate, retuse or emarginate, and seemingly always terminated by a slender tip or mucro.

The petioles are slender, smooth, varying from two or three inches in length to half an inch or less near the ends of the branches, and provided at the base with two short, comparatively stiff, awl-shaped stipules. The petiolules are thick, short, pubescent, and usually dark-colored.

The large compound racemes of flowers are much less dense and less handsome than those of *L. Sieboldi*; the individual blossoms are appreciably smaller and not generally of such a deep rich color. The calyces are smooth or covered with a short tomentum, and the bracteoles at the base appear less developed than in *L. Sieboldi*. The calyx varies from a sixth to a quarter of an inch in length, the rather obtusely pointed lobes not exceeding the length of the tube. The mature, single-seeded, flattened pod is somewhat pubescent, about one-fourth of an inch long, and a little more than half as broad. The slightly flattish rounded oblong seed is one-eighth of an inch in length and dark brown in color.

At the Arboretum, *L. bicolor*, at ten years from seed and after some annual pruning, is seven or eight feet in height and has single stems from four to six inches in circumference. These divide into several large branches at two or three feet from the ground. In good soil these plants make an annual growth of from a foot and a half to two feet, but the greater half of this growth produces flowers and does not live a second year. They now appear to have about reached their full size and development. As regards their shrubby character, they compare well with any *Colutea* in cultivation here, and, unlike *Colutea*, they do not throw up an indefinite number of stems or suckers.

In this climate the earliest flowers of *L. bicolor* open about the first week of July, and they continue to expand for about a month. The fruit is abundant and ripens early in September, and many of the pods soon fall to the ground, and if the earth is moist or they become slightly covered with soil, the seeds germinate almost immediately without leaving the pods. All the foliage is ripe and falls early in September. This species appears to be rare in cultivation.

L. Sieboldi, on the other hand, is really herbaceous,

although it has a shrubby appearance in its summer vigor and growth. The stems annually die to the ground, and, like an *Asparagus*-plant, they become more numerous each year with the age and size of the root. The first flowers do not appear here until the seed of *L. bicolor* is ripe, and many of the dry leaves remain on the stems until winter. Seed does not ripen here, but plants are easily multiplied by division.

To add to the confusion already mentioned, *L. Sieboldi* has also sometimes been called *Desmodium Japonicum* and *D. racemosum*.

Arnold Arboretum.

Foreign Correspondence.

London Letter.

CYPRIPEDIUM CHAMBERLAINII.—This is a new introduction from the east, probably New Guinea, which Messrs. Sander & Co. have recently flowered, and which has been named in compliment to the Right Honorable Joseph Chamberlain. A figure, representing a portion of the inflorescence, natural size, and a reduced picture of the whole plant, is published in the last *Gardeners' Chronicle*, along with a brief description of the plant by Mr. J. O'Brien. Messrs. Sander & Co. advertise the sale of all the plants by auction on March 4th next. I have not seen any of the living material, but the following particulars are from Mr. Sander's manager:

The plant is a robust grower with exceptionally broad leaves, in some cases fully four inches in width, undulated and tessellated, "remining one of *C. Morganæ*, but larger and finer." The flower-scapes are erect, two feet high, zigzag, and bearing numerous large boat-shaped bracts from base to apex. From each bract a flower springs, possessing scapes, some of which are said to have produced over thirty flowers. These, in color, are said to resemble *C. superbiens* or *C. Morganæ*, but in form they are quite distinct from anything else in the genus. The dorsal sepal is about two inches long and wide, yellowish white with rosy purple lines and spots. The lower sepal is similar, but smaller. The petals are each two inches or more in length, twisted spirally, tomentose and colored yellowish, with a profusion of spots and lines of a purplish color. The lip is as large, and resembles in form the common *C. spectabile* of North America; it is white spotted and shaded with rosy purple on the lower part. There are 700 plants of it advertised for sale. Besides this, at the same sale, will be offered plants of two other new *Cypripediums*—namely, *C. Kimballianum*, described as "a stately species"; the leaves are two feet long. The other has not yet been named, but it is described as having flowers like *C. Wallisi*, with a rose-colored labellum.

CATTELEYA LAWRENCIANA, the beautiful tropical species introduced from Roraima, in British Guiana, a few years ago, was sold in quantity at an auction sale to-day. This region has recently been visited by a collector from Messrs. Charlesworth, Shuttleworth & Co., who, besides the *Cattleya* and several other rare Orchids, also succeeded in bringing home alive several species of *Utricularia*.

UTRICULARIA HUMBOLDTII was among them. It has large peltate leaves and tall scapes, bearing several large blue flowers. Unfortunately, no one who has hitherto attempted the cultivation of this plant in England has succeeded in getting it to flower. It grows naturally in the heart of a large Bromeliad (*Brocchinia cordylinoides*), which always contains a quantity of water in its vase-like centre. But the same kind of treatment fails here; the healthiest plants yet obtained being grown in pans of sphagnum in a sunny tropical house. Thus treated they have made large fleshy tubers and leaves six inches across on stalks a foot high, but, so far, no flowers. Schomburgk, who visited the Roraima in 1845, saw and described this and many other beautiful plants peculiar to that mountain in his delightful book, *Botanical Reminiscences*. Of the *Utricularia* he says: "Here spread before us lay a small marshy

Fig. 18.—*Lespedeza bicolor*.—See page 112.

plain, on which Flora had assembled her most beautiful children, where the charm of flowers had culminated. The whole plain was covered with the dark blue *U. Humboldtii*, the most beautiful species of the genus, with red-tinted flower-stalks from three to four feet high, from which three or four of the curious flowers are suspended. While the amazed

eye was looking upon this charming carpet of flowers it was especially attracted by the interesting and beautiful *Heliamphora nutans*, with light green red-ribbed leaves and bearing slender drooping spikes of white and sometimes red tinged flowers."

Messrs. Veitch & Sons imported plants and seeds of the

Fig. 19.—*Lespedeza Sieboldii*.—See page 112.

Heliophora about ten years ago, but I believe the plants died, and although seedlings were raised they have not grown rapidly. One of them, however, flowered in 1890, and was figured in the *Botanical Magazine* (t. 7093). About a dozen newly imported pieces of the *Heliophora* were sold to-day. It is known as the South American Pitcher-

plant, from its resemblance to the *Sarracenias*, to which it is botanically related. The leaves are folded and horn-like, with an oblique mouth, scarcely any "lid," and when fully grown about a foot in length. The flowers are nodding, not unlike those of an *Anemone*, with scapes a foot long.

SOUTH AFRICAN FRUIT.—Some enterprising people interested in the cultivation of peaches and grapes at the Cape have recently made the experiment of importing the fruit into England at a time when they would be most likely to find a favorable market. The first consignment of peaches was sold by auction last Wednesday in Covent Garden, and realized about twenty-seven shillings per box, some fetching as much as two shillings each fruit. They arrived in splendid condition—so good, indeed, that they might easily have been mistaken for the choicest English-grown fruit. The grapes were a failure, owing, I believe, to faulty packing, and possibly to improper treatment during the voyage. I have seen and eaten grapes and peaches at the Cape, and can testify to their excellence both as regards size, finish and flavor. If the long voyage, partly through the tropics, can be made without injury to the grapes, there is a certain market for them in Europe. The fruit is as easily grown at the Cape as gooseberries are here. Of course, the result of this first experiment need not be taken as final. Even this badly packed consignment of grapes was described as being "large, well-shouldered in bunch, and full in berry." Sold by auction they realized about threepence per pound. The facilities afforded by the very fast steamers of the present time, fitted, too, with the most approved packing and store rooms, render the transport of delicate fruit, flowers and plants from distant countries much easier and cheaper than used to be possible. As a consequence, many islands and other places in the tropics which are favorable to the production of good marketable produce are being seized upon by enterprising people for the growth of fruit, flowers, seeds, etc., to be sold in Europe. The lot of the English growers is yearly becoming harder. All the skill in the world has no chance against the prodigality of nature in the tropics, combined with cheap labor properly guided.

HORTICULTURAL TRAINING.—The editorial comment on what I said with regard to this question (see page 55), namely, that if in addition to practice the pupil is instructed in some of the principles of the sciences related to the art, he ought to be a more intelligent practitioner and a broader man, cannot well be controverted. As a matter of fact this is the principle which is worked upon at Kew. Applicants are expected to take an intelligent interest in the science as well as the art of horticulture; a man who has no desire to know the reason why of his art is scarcely likely ever to rise very high in his profession. But the art, i. e., the practice, is a *sine qua non* in men who are expected to grow plants well. A knowledge of the theory alone would not enable him to do this. Nobody has ever been so foolish as to decry knowledge and thoughtfulness in horticulture. The more the better. But it will be admitted that no amount of book knowledge will enable a man to grow plants well unless he has had a practical training in the art. We only ask that practice shall be placed first; that the clever grower shall get due credit for a knowledge of his art even though he may be ignorant of the scientific principles of that art, and that the best gardener shall be he who does his work best rather than he who can talk most learnedly about it.

The Winter Garden.

IN this latitude the month of January has been one of rather moderate temperature, with no prolonged period of excessive cold and no season of warmth such as is known as the January thaw. In consequence there has been very little movement of vegetation, and even the precocious Chickweed has not as yet shown flower in the garden. However, the garden has at no time been entirely bare of flowers. The autumnal Snowdrops still preserved their forms till early in the new year, when Elwes' Snowdrops began to show color, and stray plants of *Anemone blanda* greeted the lengthening days with their cheerful stars. During February these Snowdrops preserved their purity through all changes of weather, and have been gradually joined by other varieties—*Galanthus plicatus*, *G. Fos-*

teri and *G. umbricus*. Some stray blooms of *Scillas* make dainty spots of blue in the border, and the first of the *reticulata* group of *Irises*, *I. Bakeriana*, has been true to its season. A few warm days will bring forward others of the group, with some varieties of *Anemone*, to be followed soon by the rush of spring flowers.

It may as well be repeated that the flowers named are true winter flowers, and are as well adapted by their structure for their winter environments as any summer flower is adapted to its season. As a matter of fact, if protected from blasting north-west winds, they have an endurance beyond that of most flowers of other seasons. On the 4th of January I noticed the first *Anemone blanda*, which had been encouraged into growth in a warm corner by the edge of a mat overhanging a frame. That same flower, now early in March, opens up its face to the sun every bright day, as pure and unscathed as at first. The *Snowdrop* hides a capacity for heroic endurance under a form of the most captivating fragility and helplessness. The *reticulata* *Irises* vary somewhat, and if the buds are caught in a certain state by an extreme frost they may be injured, but when expanded they endure for a number of days. Over these flowers it is well to secure a sash or some contrivance to throw off wet, but they need no coddling from the cold. At this moment my flowers are under the snow, but the first warm day will reveal them again unsullied and as bright as ever. A succession of *Snowdrops*, *Anemones*, *Scillas*, *Muscari*, *Crocuses*, *Chionodoxas*, *Irises*, *Fritillarias*, *Aconites*, etc., will carry forward the season to the first *Narcissi* and large-flowered bulbs, which later fill the garden with gay blooms. Of course, these small flowers, even in considerable colonies, are not showy, and do not make much impression on the general bareness of the garden, but they are distinctly pleasing and always interesting, and these are qualities we should insist on in a plant as well as in a friend.

One of the pleasures in making a winter and early spring garden is the constant study and experiment required and the difficulty of securing choice material, with the harassing doubt at first as to results. Such a garden is never finished. One gains new points every season to be put on trial, and is pleased if every year shows some slight gain. At present my small bulbs are planted in clumps, with clumps of *Narcissi* for succession. Over all is sown a sprinkling of *Poppy-seed*, for the summer succession. The roots of these latter plants run deep, and should help to keep the ground sweet. It is, of course, a drawback to bulb-culture that beds must be primarily devoted to them, and it is better to suffer the sight of bare earth rather than cover with vegetation which will interfere with the ripening. A bed of this kind is not protected during the winter by any covering, plants of at all doubtful hardiness being in other quarters. Most of these plants are also capital subjects for a cold house. As suggested a few weeks since, a pan of *Snowdrops*, thickly planted, is very attractive, and the plants will be furnished with better foliage than in the open. *Iris reticulata* forces about as readily as any bulbous plant, and its pleasant Violet-like odor is very pronounced under glass. There is much difference in the beauty of the flowers of this *Iris*, those of a reddish cast being not attractive. If one has a cool house from which frost is just excluded, plants of the character under discussion can be grown very effectively and satisfactorily in a rockery, on which can also be arranged some of the small alpine which suffer out-of-doors from the winter rains.

Elizabeth, N. J.

J. N. Gerard.

Variegated *Abutilon Eclipse*.

THIS must not be confused with another *Abutilon* named *Eclipse*, a large variety with green leaves and flowers, orange-colored, veined with crimson and purple. The latter plant is a standard variety in England, though not common in this country. The variegated one is very distinct and beautiful, resembling *A. vexillarium* in type, being of trailing habit and most useful as a pillar-plant for the greenhouse and conservatory. Trained loosely, so as to allow the side branches to droop, it is very effective, as it bloom in the winter, when its graceful branches are loaded with lovely bell-shaped flowers of orange-yellow, with sepals of reddish brown. The leaves are mottled with bright yellow and deep green, and the variegation is most distinct in the winter months when the sun is not so strong, and this makes it more useful.

One of the best modes of culture is to grow it as a standard, using any of the ordinary varieties for stocks, and budding or grafting at the desired height. The stock requires to be grown to a single stem, and kept tied to a straight stick until strong enough to support itself. Two and a half or three feet is tall enough, when the top should be pinched off so as to afford

stiffer and harder growth for budding. This is better done in the spring in a greenhouse, where the plant can be kept in a moderate temperature and partially shaded. If no currents of dry air are admitted—that is, if the house is not too freely ventilated—the buds will “take” in about two weeks. When union is effected, the growth of the stock should be restricted, pinched and kept back, to throw strength into the new growth of the buds, but it should not be stripped of leaves until the buds have made considerable growth, so that the roots are kept active and no check is given the plant. Such plants will make good specimens for the next winter. Eclipse is of better habit than *A. vexillarium* and forms a bushy top. If any shoots are straggling pinch them back, and they will break and become more bushy. The plants may be kept in pots or planted out during the summer and potted in the fall. During the winter months they will produce profusely axillary flowers in clusters to the tips of the branches and make a striking display. The plant is also an excellent one for bedding out, and it makes a good edging to groups of large plants. For baskets or vases it cannot be surpassed. Cuttings of the young wood strike readily at any season. The ordinary soil for greenhouse-plants will answer well for this *Abutilon*. When the pots are full of roots an occasional watering with liquid-manure will prove beneficial.

Cypripedium Leeanum and Varieties.

OF the many fine hybrids which have been obtained artificially by fertilizing one species of *Cypripedium* with the pollen of another the subject of this note is one of the best and most generally useful. There is hardly a flower-show throughout the year, at which it is customary to exhibit Orchids, where *C. Leeanum* is not represented by numerous varieties. This is sufficient evidence of the free-blooming quality of this plant, and the flowers when cut will keep a fortnight.

Like many other fine hybrids, *C. Leeanum* was produced in the nurseries of Messrs. Veitch, of Chelsea, the parents being *C. insigne* and *C. Spicerianum*. The flowers first expanded in January, 1854, and were exhibited at the Royal Horticultural Society in the same month. A glance at the flowers suffices to show that both parents are represented in their offspring, which for size and beauty of color surpasses both. The upper sepal, which possesses the peculiar fan-shaped overhanging properties of *C. Spicerianum*, is almost entirely pure white, with the exception of a bright green blotch at the base, from which radiate upward and outward rows of mauve-purple spots. The lower sepal is much smaller, but still of a fair size, and is pale green with two rows of dark red spots running more than half-way down the inner surface. The petals partake of the characters of those of *C. insigne* and *C. Spicerianum*, the upper margin being for half its distance wavy. The surface is greenish yellow with a conspicuous purple-brown line down the centre, while there are numerous dark spots at the base. The lip is a deep glossy purple-brown, exhibiting a reddish tinge here and there, according as the light strikes it. The incurved lobes, however, are a pale buff-yellow, as is also the large crinkled staminode, in the midst of which is a lemon-colored knob surrounded by numerous minute warts, the tips of which sparkle in the light.

Of the numerous varieties the most worthy of notice are *Superbum*, *Giganteum* and *Masereelianum*. The first is tolerably well known by its large upper sepal and distinct blotches; the second is a still larger form, with the same characteristics, while the third—*Masereelianum*—is the most distinct of all, and may at once be recognized by the conspicuous ivy-green blotch at the base of the upper sepal, which is decorated in the same way, only with larger spots, as the variety *Superbum*.

The same treatment accorded to *C. Spicerianum* will suit *C. Leeanum*.

Islsworth, London.

John Weathers.

Insects in the Soil of Greenhouses.

DURING the present winter much complaint has been made that the soil in many greenhouses is so completely infested by insects that plants fail. This not only in private conservatories, but among gardeners who raise flowers for market and in the forcing-houses of truckers. From a considerable number of samples of soil seen, I find that the insects are nearly always either podurids, maggots or fly larvæ, or myriapods. The podurids are minute insects, usually brown in color, furnished with a pair of anal styles, by means of which they leap about quite actively. They sometimes occur in the soil in perfectly astounding numbers. In one case, where on

a warm sunny day the house was opened, they crowded the surface one-quarter of an inch thick, and about two ounces of specimens were brought me. As the specimens are less than one-sixteenth of an inch in length, and of no perceptible diameter, the number can be only guessed at by millions. These insects feed on decaying vegetable matter in moist, warm places. They are lowly organized, and of a scavenger character. The fly larva was that of a muscid, not one of the root-maggots, and was always associated with rotting manure. The myriapods, finally, were either cylindrical forms like *Iulus*, or somewhat flattened forms like *Polydesmus*, and in all cases lovers of warm moist places, and, normally, feeders on decaying vegetation. These creatures were usually described as wire-worms, while the podurids figured as lice, and much of the failure of plants was charged to them. The podurids and fly larvæ were innocent; but there is good evidence that the myriapods did some gnawing of Rose-roots, and perhaps of those of other plants as well. It will be noted that all of these insects are, primarily, feeders on decaying matter, and this decay is provided in any quantity by the manure used to enrich the soil. This abundant nourishment, combined with an equable warm temperature and a moist atmosphere promoting decay, furnishes ideal surroundings for these insects, and they multiply accordingly. When the soil becomes filled, every injured root and every dying rootlet becomes a point of attack, and they promote decay by keeping bare and irritated every point of injury. The remedy is simple. Apply some of the needed nitrogen in the form of nitrate of soda, and some of the needed potash in the form of kainit. Put the kainit into the ground before you set out your plants, and your nitrate when you want the plants to do best. Both these substances are soluble in water, and can be put into pots in solution. None of the insects mentioned can live in a soil impregnated by these minerals, while as fertilizers they are worth all they cost. In other words, reduce the amount of decaying matter in the soil, and add the needed elements in some directions by using the minerals themselves. It is the salt in its combination in the nitrate and kainit that has the insecticide effect; but common salt is not as effective in the form in which the chloride is combined as it is in the kainit.

John B. Smith.

Sowing Celery-seed.

MANY amateur gardeners have so much difficulty in getting a good germination of Celery-seed that they have abandoned the effort and buy their plants.

This may be the best course when only a few plants are wanted, but it is easy to get the plants from seed with proper treatment. My plan, which has never failed, even in hot-weather sowing, which is essential here, where early sown plants would run to seed in fall, is as follows: Celery-seed, being quite small and their first growth delicate, will not bear heavy covering of earth, and a light cover in our brilliant sunshine soon becomes so dry that germination is retarded; I therefore sow on a well-prepared border on the north side of a board-fence. The rows are barely traced across the bed, and the seed scattered thinly on the lines. The whole bed is then beaten over with the back of the spade, which gives sufficient cover. I then cover the surface with old gummy sacks or cotton baling. This prevents the drying of the surface and insures a uniform germination. As soon as the seeds sprout the cover is raised on sticks and gradually removed as they show green leaves and can bear exposure to the light.

As soon as the plants are large enough to handle easily I transplant them to a cold frame and cover the frame, in lieu of sashes, with screens made of laths tacked an inch apart. This gives a varying shade, and the plants thrive wonderfully and will need to have their tops sheared once or twice before final transplanting.

The time for sowing the main, or winter, crop would be late in March in latitude of New York, and in late May in North Carolina, and the final transplanting in July and September respectively.

Raleigh, N. C.

W. F. Massey.

Aster acris.—This is one of the most useful of the dwarf forms of perennial Aster, or Michaelmas Daisy. It is a delightful plant to produce a gay mass of color, and should be used freely to color the garden-scenery in the fall months. The habit of the plant is quite dwarf, and even in rich soil the growth does not rise more than two and a half feet, the leafage in the autumn, from the middle of September until early October, being hidden beneath the mass of light purple flowers. I have seen this variety produce beautiful pictures in the

autumn, and associates well with the early-blooming section of *Chrysanthemums* best represented by the variety *Madame Desgranges*, the Daisy forming the outer ring to the bed, the centre filled up with the *Chrysanthemum*. Both grow freely in ordinary soil.

Kew.

Constitutional Health of Plants.

To the Editor of GARDEN AND FOREST:

Sir,—Observing the growths of the various plants we notice that some of them are unthrifty, and when closely inspected we find them infested by microscopic parasites. Other plants we see preyed upon by insects, which, like the fungi, eat the substance of the plant. We may also notice other plants, growing under apparently similar conditions, but free from fungus or insect, and apparently healthy in the midst of pestilential influences.

Fungi and insects evidently choose their food, and where there is a choice of adaptable foods they often show a decided preference. The potato-beetle feeds upon the Egg-plant, the Tomato-plant and the Potato-plant, but, where all of these are equally accessible, the Potato-plant will be chosen the first. The rose-bug feeds upon all sorts of Grape-vines, but it prefers those containing the blood of *Vitis riparia*, and where it finds some of these vines in the vineyard it will feed chiefly upon them, nor eat of other vines until these are devoured. Hence viticulturists advise the interspersing of a few *Riparia*-vines in the vineyard to attract this insect from other varieties.

Just as higher plants refuse to grow in some soils and thrive in others, fungi show their preferences for one or another host-plant. The black rot of the Grape infests almost all varieties of the vine, yet among them the omnipresent spores of this parasite manifest this elective affinity in a remarkable way. For example, in ordinary seasons favorable to thrift of the vine and unfavorable to activity of this fungus, the Ives are comparatively exempt from attacks of this so-called disease. Yet vineyards of the Ives are sometimes ravaged by the black rot, proving that this variety of *Vitis Labrusca* is not specifically resistant to the fungus. But in the behavior of the fungus with relation to this vine we have interesting proof of the action of those subtle preferences, already alluded to as elective affinities. In 1873, when the grape rot first became severely epidemic in southern New Jersey, I noticed in one of my vineyards a few Ives Grape-vines free from the disease, while surrounding Concords were all rotting. Soon afterward, in a report from the state of Illinois, I was informed that "the Ives grape does not rot." I then procured Ives vines, and in a small vineyard of five hundred Concords, set twelve feet apart along the rows, I planted Ives vines intermediately with the Concords, purposing, if the latter proved unsatisfactory, finally to extirpate them. At the same time I planted another vineyard of two thousand Ives vines. All of these vines, Ives and Concord, came in fruit together. Grape rot was epidemic, and destructive to the Concord. In the vineyard of mixed Ives and Concord the latter all rotted, while the Ives grapes did not rot at all. The vines of both sorts interlaced on the trellis, and here were clusters of Concord totally ruined by rot, while among them, and almost touching them, were clusters of Ives completely healthy. In this mixed vineyard this phenomenon of diseased Concords and healthy Ives has been yearly manifest.

On the other hand, in the vineyard where two thousand Ives are planted by themselves, there is yearly more or less of grape rot, appearing sporadically, but never so badly as on Concord-vines. When this Ives vineyard was planted, a few vines failed to grow; these were replaced by Concords. When the latter came in fruit the rot took full possession of them, while the Ives growing nearest to the rotting Concords were the healthiest of any of the Ives-vines in the vineyard. It looked almost as if the germs of the rot fungus were endowed with the power of motion, and had abandoned the Ives vines to feed upon the Concords.

Certainly each minute organism has its own peculiar way of propagating its species, and in getting a living makes choice of congenial foods. Now, since this choice of food is directed by some peculiar quality in the juices or tissue of the plant which are attractive to these devourers, or else repellent to them, it may be possible by an enlightened use of special fertilization, or by medication, to influence or modify the qualities of cultivated plants, so as to render them unattractive to these aggressors. Why is it impossible for science to discover prophylactics for the diseases of plants as it has done for contagious diseases of animals? Such prophylactics might be adminis-

tered through the natural channels of absorption with plant-food. Or if the subtle germ or virus productive of disease can be transmitted from plant to plant by inoculation, as in the case of Peach yellow, perhaps the antidotes (when we discover them) may be also thus applied.

Experience shows that plants stimulated into vigorous growth by special fertilizers are often peculiarly exempt from the attacks of insects and of fungi. Evidently, there is that in the juices of such plants which does not please their taste. I planted some Potatoes on poor soil, where they made but feeble growth. Near this plot was one planted with similar Potatoes, fully fertilized, and stimulated by nitrogenous manures. The weak plants on the poor soil were attacked by the beetle and devoured before the strong plants were touched. This is ordinarily explained by saying that the fertilized plant grows faster than the bug can eat it; but, in fact, the beetles did not visit these plants. When they had consumed the plot of weaker plants they sought other fields of similarly starved Potatoes and ate these in preference.

These two Potato-plots also showed a remarkable contrast in resistance to the Potato-blight, which, when it became epidemic, attacked the weaker ones first and totally killed them. The stronger plants were blighted later, but the leaves only were harmed. The stalks were unaffected, and, after the foliage perished under the fungus, they put forth a new growth, which endured until frost, maturing a crop of tubers. Evidently, fertilization promotes the health of the Potato-plant, and enables it to resist some diseases. There is reason to hope that when we shall have learned how to feed the plant with all of the requisites to health, we may secure more complete exemption from contagious disease.

Vineland, N. J.

A. W. Pearson.

The Tan Bark Oak.

To the Editor of GARDEN AND FOREST:

Sir,—Among Californian Oaks, and there are many, none are more beautiful than *Quercus densiflora*. It is an evergreen, and forms in appearance a connecting link between the Oak and the Chestnut. The leaves, elliptical in outline, light green above and fuzzy beneath, are shed in summer. In July it blossoms, and the very fetid odor of the flowers is the one disagreeable trait of this fine tree. It bears a true acorn, oblong in shape, set in a shallow cup, which, on account of long, slender light green scales, seems moss-covered. The bark is thick and rough, exceedingly rich in tannin. The wood is straight-grained and tough, excellent for fuel, and will, in all probability, be found valuable to the wood-worker. It ranges from Monterey County north to Mount Shasta, in the Coast-range of California, being pretty closely confined to the Redwood belt. At Mount Shasta it grows as a bush five to eight feet high, covering considerable areas.

It is in the Redwood region that it attains its greatest perfection, and it is everywhere a tree of the mountains. On the open ridges the Tan Bark Oak is a great spreading tree, frequently three feet in diameter and fifty in height.

The dense shade of the Redwood forest forces every tree to grow up for light and air, and in such situations this Oak grows as erect as a Pine, almost bare of branches for two-thirds its height, seldom over two feet in diameter and frequently sixty to eighty in height.

It is on the eastern or interior edge of the Redwood belt that it is most abundant, forming the principal growth on the ridges, and preponderating on the upper slopes. Its commercial value is great, and the demand so much that it is now being hauled by wagon twenty to thirty miles over rough mountain-roads to reach the railroads or sea-coast, and large areas are stripped annually. Nearly all of these mountain-roads follow the ridges, enabling the bark-peelers to secure the bark readily along not only the main ridges, but the laterals.

The workers, with their families, move out into the woods for the summer. A Redwood is cut, and the lumber split out for the cabins, sheds, stables, and even the board chimneys. A few lengths of one of these big trees will split into enough lumber to build quite a settlement. The Oaks are cut close to the ground, and the bark scored off into four-foot lengths. It is then peeled and thrown down to dry. When dry it rolls. The hill-sides are very steep, and to get this bark to the wood-roads hand-sleds are used. In some places where wood-roads would be expensive, pack-mules have been used.

Nothing but the bark is used, and after the peelers have gone through a maze of trunk and branch covers the ground, to rot or be burned by the next forest-fire. Of course, the wood is used for fuel in some few places accessible to shipping-points, but it may be said safely that not one-tenth is so

used. When a fire sweeps through this mass of dry material it burns with a heat that kills small standing trees. In peeling the methods are wasteful, and very often a tree may be seen that some lazy peeler has girdled by taking a four-foot section of bark from the base. The Tan Bark Oak is tenacious of life, and sprouts vigorously, but the odds are against it, and it seems as if in a few years this fine growth, whose future value, on even a cord-wood basis, would be immense, will be destroyed to secure a few lengths of bark from each tree.

Ukiah, Cal.

Carl Purdy.

Help Against the Gypsy Moth.

To the Editor of GARDEN AND FOREST :

Sir,—In view of the success which has apparently crowned the efforts of the Orange culturists of California in "fighting fire with fire," or rather insect with insect, and, calling to mind the warfare which is being waged in the vicinity of Boston with the Gypsy Moth, I was struck with a passage I was reading to-day in a little book entitled *The Branch Builders*, by the late Rev. J. G. Wood, which, if my memory is not at fault, is a reprint of a portion of his better-known work, *Homes without Hands*, and which may perhaps suggest a new method of meeting the invader.

In treating of the habits of an English species akin to our tent-caterpillar, he speaks of a carnivorous beetle, the larvæ of which are often found in the nests of this pest, and which feeds voraciously on the caterpillar. The scientific name of this beetle he gives as *Calosoma sycophanta*.

The following extract will show its connection with the case in hand :

"Knowing the habits of this grub, a French entomologist, Monsieur Boisgerard, managed very ingeniously to avail himself of its devouring capacities. There is a well-known insect, the Gypsy Moth, which is very common in France. The larvæ of this moth are destructive to trees, feeding on their leaves, and then retreating to a hiding-place in some crevice of the bark. Finding his trees infested with these caterpillars, Monsieur Boisgerard procured a number of female *Calosomas*, and placed them on the trees. They laid their eggs, and in due season the larvæ were hatched. In process of time the destructive grubs increased so much that they ate all the noxious caterpillars, and at the end of the third year the trees were cleared, and the *Calosoma* beetles had to go elsewhere for a living."

"In England the *Calosoma* is very rare," but "in the south of France it is plentiful enough, as is needed from the enormous multitudes of crop-destroying caterpillars on which it feeds."

This plan may already have been tried or investigated, but if not, it seems to me worthy of consideration, though I am aware that the introduction of foreign species of animals is not to be lightly entered into; witness, the English sparrow and the rabbits of Australia.

Minneapolis, Minn.

Frank H. Nutter.

[There is no doubt that certain ground-beetle larvæ feed upon hairy caterpillars, and the observation mentioned is correct. Professor Riley writes that he has for some time been urging the Gypsy Moth Commission to send an agent abroad to collect the European enemies of that insect, and it is to be hoped that this will soon be done.—ED.]

Exhibitions.

Orchids at Short Hills, New Jersey.

THE exhibition at the United States Nurseries, to which Messrs. Pitcher & Manda invited the public last week, surpassed in richness of material and effectiveness of arrangement any of the previous efforts of the firm. The main display was arranged in the great Palm-house, 250 feet long and high enough to accommodate superb specimens of Tree Ferns and Palms. The visitor entered the house through a vestibule flanked by tall Laurels and *Cytisus* in bloom, with the clear golden yellow of *Doronicums* on either side of the doorway. Inside the door there seemed to stretch away to an interminable distance a tropical forest, with its shady vistas brightened by the flowers of thousands of Orchids, not crowded together, but naturally and effectively placed where their soft harmonies and contrasts would make the most pleasing picture. On either side of this long house, and opening into it at right angles, were other houses, making altogether a cluster of twenty, each one of which was a study. One of them, for example,

was entirely filled with *Areca lutescens*; a second with *Adiantums*; a third with *Pandanus*, and a fourth with *Phoenix*. *Dra-cænas* filled another, and *Areca Baueri* another still; and one which contained nothing but *Anthuriums* and *Bromeliads* faced another filled with *Kentias* and *Cocos*.

It would be useless to attempt a description of all the rare and beautiful Orchids that were scattered among the greenery of the great house. To name them even would be a task, as the list would include most of the principal species and varieties in flower at this season which are prized in the great collections of the world. There were some 3,000 plants in bloom. But among those which were particularly attractive we noted a vigorous specimen of the white *Cœlogyne cristata*. Near it was the dainty little *Epidendrum Endresi*, and farther on were the long white and fragrant spikes of *Dendrochilum gluma-ceum*. On a stage about a huge *Chamærops* were grouped fifteen specimens of the white *Lycaste Skinneri*, and fifty of these snowy flowers are not often seen together. Among the *Dendrobiums* was a strong plant of *D. splendidissimum grandiflorum*, and suspended from one of the Palms was as fine a piece of *Angræcum sesquipedale* as we have ever seen, with its deep waxy cream-colored blossoms. Among the most interesting of the different varieties of *Cattleya Trianae* was Lee's variety, not only rare, but wonderful for the depth and richness of its color. *C. speciosissima* was represented by a variety remarkable for its size and for the delicacy of its pale lilac blossoms. An interesting place to linger was among the many distinct varieties of *Odontoglossum crispum*, and near these was a plant of *O. Rukerianum* with two large spikes and fifty flowers.

One of the houses opening into the Palm-house was full of *Cypripediums*, which occupied both the centre stage and side benches, with no plants among them except small *Araucarias* and one row of tall ones in the centre to soften the color. There were one hundred and twenty-six varieties here in bloom, and more than five hundred plants. They were all seen to good advantage, as the plants were separated by the soft green foliage of the *Araucarias*. Perhaps the experts in *Cypripediums* would find the greatest delight in such specimens as one of *Cypripedium Sallieri Heyanum*, which was offered at \$800, or another of *C. pavoninum*, or a third of *C. Germinyanum*. But besides such varieties were beautiful specimens of *C. villosum* and other standard species in almost infinite variety. Among the new hybrids in bloom was one named *Beatrice*, a cross between *C. Boxalii* and *C. Lowii*, and another between *C. venustum* and a form of *C. insigne*. *C. Lindleyanum* was represented by an admirable plant with a spike more than three feet long.

Of course, the Orchids were the chief attraction, but the house which was filled with *Azaleas*, *Cytisus* and bulbous plants in bloom was exceedingly bright in color, and the single block of houses massed on this part of the grounds had plants enough to keep one occupied a day if he gave them more than a cursory examination. After all, the most interesting exhibition at Short Hills is the order and cleanliness and good taste shown throughout all of the fifty houses now in operation. The great stretches of plants in every stage of growth, from the tender seedling up to the display specimens, all show good health and careful cultivation, while all the operations and processes of the immense establishment move on with apparent smoothness and ease. Of Orchids alone there are said to be here some 1,200 distinct species and botanical varieties, at least 400 horticultural varieties, and perhaps as many artificial hybrids. There are 3,000 seedlings growing, some of them hybrids between different genera.

Orchids at the Eden Musée.

FOR the sixth year in succession Messrs. Siebrecht & Wadley have held an exhibition of Orchids and other tropical plants at the Eden Musée, in this city. The chief interest of the exhibition, as usual, centred in the Orchids, which were shown in considerable variety, but first-rate specimens of Palms, Cycads, Tree Ferns and other rare and valuable tropical plants were also displayed. Many of these last were said to have been lately brought from Trinidad, where there is a branch of the Rose Hill Nurseries, in which tropical plants are produced in large quantities. The plants were arranged with good taste, especially the curtain of greenery which masked the front of the balcony. One of the most interesting Orchids in Messrs. Siebrecht & Wadley's collection was a new form of *Cattleya labiata* which had a larger lip, a deeper color, and was altogether of thicker texture than the original type. There were good plants of *Cattleya splendidissima*, *C. Schroederæ* and *C. Aspasia*, and many other choice forms of *C.*

Trianae. *Cymbidium Lowii* was represented by some well-grown specimens.

Mr. W. S. Kimball, of Rochester, had a remarkable group of Cypripediums, among them being fine examples of *C. Argus*, *C. Boxallii atratum*, *C. Calurum*, *C. Winnianum*, and fifty others. The new variety, *C. Lathamianum*, was seen for the first time by a good many visitors. Mr. F. H. Goodrich also showed some admirable specimen plants, one of *Odontoglossum grande* attracting the most attention. The collection of Mr. Hicks Arnold was represented by a magnificent spike of *Dendrobium Phalaenopsis Schroederianum*, blooms of *Cypripedium microchilum*, *C. Lathamianum*, and many other choice species. Mention should also be made of a wonderful specimen of the true *Cattleya Trianae alba*, the genuine snow-white form, which is so rarely seen. Apart from the Orchids, two magnificent plants of *Licuala grandis* and some admirable *Crotons* were the most attractive things in the exhibition.

Since the last exhibition some changes have been made in the hall, and they do not seem to have improved it as a place for displaying plants and flowers to the best advantage. It was a misfortune, too, that the proprietors of the Eden Musée were unable or unwilling to furnish a better light in the evening. When the owners of fine plants go to the trouble and expense of transporting them a long distance, besides sending competent persons to superintend their arrangement, it is worse than annoying to have their beauty hidden in darkness.

Notes.

Mr. John N. May writes to the *American Florist* that throughout the entire eastern section of the country there is complaint that Roses are not producing as well as usual this year.

The third southern California Citrus Fair, now open in Los Angeles, is said to surpass all its predecessors in variety and beauty of exhibits. Tourists who may be passing through Los Angeles are advised by a correspondent of *The Tribune* to see this fair, as it demonstrates the important work being done for the improvement of oranges and lemons. One of the features of the display is the new seedless lemon, which promises to rival in popularity the navel orange.

Number 2,000 of the *Gardeners' Magazine*, its issue for February 27th, has just been received. This journal was started on the 1st of March, 1833, as a sixpenny monthly, under the name of the *Floricultural Cabinet*, by Mr. Joseph Harrison. His sons carried on the paper until 1859, when it was changed to a weekly under its present title. In 1861 Mr. Shirley Hibberd became its editor, and continued to occupy that post until his death, in November, 1890. Mr. Hibberd was succeeded by Mr. George Gordon, who was associated with him in the literary management of the paper for many years. A horticultural journal, with an honorable history of nearly sixty years behind it, is worthy of respect, and deserves the best wishes of all lovers of the art which it represents.

The bill to incorporate the Yellowstone Park Company, to which editorial allusion was made in last week's issue, was referred to Secretary Noble for his opinion, and he has sent to the chairman of the committee which holds the bill an energetic protest against it. After criticising it in detail, he characterizes it as opposed to the public good, for private interests solely, and in every way pernicious. He expresses the opinion that, in view of the growing interest in the park, the Government should strengthen its control over it rather than substitute a corporation in its place and compel the people to feel at every stage of progress amid these wonders that they are there to help a private enterprise rather than to enjoy their own under the control and responsibility of the National Government.

On the German seed-farms labor is very cheap. The average wages of a workingman is from seven to nine shillings a week, and for this he works from five in the morning to seven in the evening, and in winter one hour less, commencing at six instead of five. In summer the hands are employed in the seed-grounds, and during the winter months in the warehouses cleaning and dressing seeds. Much of the lighter field work, such as hoeing, cleaning and gathering seed, is done by women and girls, who work in gangs under the charge of a foreman. They are very expert in the use of the hoe, and get over nearly as much ground as a man. They earn from tenpence to one shilling per day, and many have to walk several miles to and from work, as the majority live in the surrounding villages.

Mr. J. M. Samuels, Chief of the Department of Horticulture for the Columbian Fair, writes to the press that P. S. Peterson,

a nurseryman of Rose Hill, Chicago, has during the past week planted six trees on the grounds near the horticultural building, as a permanent exhibit, and as a practical illustration of the successful methods of transplanting large ornamental trees. They are an Elm, fifty feet high and two feet in diameter, brought from the woods in 1876, when fifty years old, and planted on the nursery grounds at Rose Hill; a Hackberry, forty feet high and two feet in diameter, also transplanted from the woods in 1876; a Linden, forty feet high and a trunk eighteen inches through; a Willow, thirty feet high and thirty feet spread; a Sugar Maple, forty feet high; an Ash, thirty-five feet high. It required a force of twenty-two men and twelve horses to transplant the trees, and the cost of the work was about \$700.

Surprise is expressed in *Meehans' Monthly* that the English Heath is not more generally cultivated in the United States. It has been in prominent American nursery catalogues for many years, but the demand for it is small, because people do not know that it may be cultivated readily. The great enemy to it is the sun when the thermometer is very low. It would grow near the North Pole, with a light covering of leaves, snow or anything that would protect it from the sun. It will not grow in heavy clay or in any soil where the earth packs closely together, as the small hair-like roots cannot penetrate this stiff matrix; but wherever the soil is sandy, gravelly, or in any way so constituted that the little roots can push freely, it grows well. It is a good plan to enclose a plant in a four-sided frame, such as a soap-box without a bottom, and fill in three to four inches of sand so that it gets in among the lower branches. The plant seems to thrive even better under such circumstances than on its native heaths.

"There are certain flowers," says Mr. Conder in his book on Japanese flowers, "which bloom twice in the same year. These are technically called Returning Flowers. Though considered unsuitable for ordinary occasions, because out of harmony with the season, such flowers are especially appropriate for farewell gatherings. The idea in so employing them is to express the hope for a safe return. . . . Flowers placed before sick persons should be put together in a rapid and unlabored manner, and should be vigorous in style, to suggest the idea of recovery and strength. At the ceremony of praying for the sick flower-compositions should be full and gay, as well as bold and powerful in style. . . . As it is the east wind which brings rain, floral arrangements used at time of praying for rain should have their principal line pointing from right to left, to suggest the east wind blowing; a reverse arrangement is resorted to on occasions of prayer for fine weather, when the principal line, leaning from left to right, is made to suggest the west wind.

Among the investigations of timber undertaken by the Department of Agriculture was a series of tests to determine the effect of gathering resin from Long-leaf Pine upon the strength of the timber. It has been believed that timber from trees which have been "boxed," sometimes known as "Turpentine timber," loses both durability and strength. There can be little doubt that the withdrawal of the resin, which keeps out water, and has apparently some antiseptic qualities, does reduce the capacity of the timber to withstand rot. But the tests so far carried on seem to indicate that turpentine timber possesses greater strength than that from unboxed trees. Of course, this result is not to be accepted without further verification, but the matter has seemed to Mr. Fernow of sufficient importance to justify a circular giving the conclusions of Professor J. B. Johnson, who is conducting the experiments at St. Louis. In a general way these conclusions are that turpentine timber exhibits less tensile and shearing strength, but it is stiffer and has greater compressive strength endwise and greater cross-breaking strength. The turpentine timber proved harder to work, however, since the resin seemed to be collected in spots, and gummed up the tools.

Catalogues Received.

BULB GROWERS' ASSOCIATION, Bayonne, N. J.; Price-list of Summer-flowering bulbs and Seeds.—CHIPMAN BROTHERS, Sandwich, Cape Cod, Mass.; The Cape Cod Pond Lily.—M. CRAWFORD, Cuyahoga Falls, O.; New Strawberries.—EMERSON, SMITH & Co., Beaver Falls, Pa.; Saws.—FRED. W. KELSEY, 145 Broadway, New York; Choice Hardy Trees and Plants.—E. W. REID, Bridgeport, O.; "Everything for the Fruit Grower," Price-list of Select and Tested Seeds.—J. C. VAUGHAN, Chicago, Ill.; Trade-list for Florists.—JAS. E. WARNER, 19 Park Place, New York; The Thermo-static Incubator.—H. W. WILLIAMS & SONS, Batavia, Ill.; Tree and Plant Labels, Transplanting Boxes and other Supplies for Nurserymen and Florists.

Serenio Watson.

SERENIO WATSON, the Curator of the Herbarium of Harvard College, a man of high character and sound learning, and since the death of Asa Gray the foremost systematic botanist in America, died at his home in Cambridge on the 9th instant after a long and painful illness. He was born on the 1st of December, 1826, at East Windsor Hill, Connecticut, one of the youngest of a large family, and graduated in 1847 from Yale College; then, having taught school for several years in different states, he studied medicine at the University of New York, and later, with an older brother, established as a physician at Quincy, Illinois. He practiced his profession for two years, and then abandoned it to become Secretary of the Planters' Insurance Company of Greenboro', Alabama, a position which he occupied from 1856 to 1861. It was at this time that Mr. Watson began seriously to study plants, although it was not until seven years later, after a term in the Sheffield Scientific School, that he became a professional botanist. He was in California in 1868, and sought and obtained the position of botanist to the United States Geological Expedition, which, under the leadership of Clarence King, explored the territory in western America adjacent to the fortieth parallel of latitude. He was engaged in field-work principally in central Nevada and Utah during the seasons of 1868 and 1869, and published in 1871, with the aid of Professor Eaton, the results of his investigations of the flora of the Great Basin, his report forming the fifth volume of King's *Report of the Geological Exploration of the Fortieth Parallel*. Watson was now invited by Professor Gray to become his assistant at Cambridge, and the remainder of his life has been devoted to the study of the flora of North America and to the care and improvement of the Gray Herbarium and Library.

His publications since his connection with Harvard College have been important; they consist of *The Botany of California*, in connection with Professor Wm. H. Brewer and several specialists; of eighteen numbers of *Contributions to North American Botany*, chiefly published in the

Proceedings of the American Academy of Arts and Science, and containing the descriptions of many new species of plants and the elaboration of various groups and genera; and of the first part of the *Bibliographical Index to North American Botany*, a most useful work of much research and learning, in which are cited the authorities for all American plants, with a chronological arrangement of their synonymy. Mr. Watson edited the unpublished work on North American Mosses of Lesquereux and James, and more recently, with Professor Coulter, a new edition of Gray's *Manual of the Botany of the United States*. He was a valued contributor to the columns of this journal, and the earlier volumes contain his descriptions of many new and interesting plants. On the death of Professor Gray, four years ago, Mr. Watson was made curator of the Gray Herbarium and Library, and the last years of his life have been spent in administering these great collections, which make Harvard one of the important centres of botanical research.

Mr. Watson was a silent man, retiring and self-contained, always genial and kind, of marvelous capacity for sustained labor, and untiring in helping others. This is not the occasion to discuss his position among the botanists of the period; and just now our thoughts are full of the man, the old and trusted friend and associate, whose death takes from us the example and inspiration of a modest and well-spent life of noble endeavor and useful labor.

The Golden-leaved Oak of California.

THE great forests of California, those that clothe the slopes of the mountain-ranges, which extend in parallel lines through the state from its northern boundary, where the two mountain systems are joined by cross-ranges, almost to its southern limits, are chiefly composed of coniferous trees—Pines, Firs, Spruces and Sequoias; and these so predominate that the facts are often overlooked that within the borders of the state are found some of the noblest broad-leaved trees which grow outside the tropics, and that California is the home of the handsomest and the largest, if not the most valuable, Oaks of the New World. They make the valleys parks, dot the low foot-hills and climb high up the mountain-sides; some retain their foliage for more than a year, and others renew it every spring; some are great trees and others are little shrubs; sometimes an individual of a species attains enormous dimensions, and sometimes under different conditions of environment another individual of the same species is only able to raise a few stunted stems a foot or two from the ground. On certain individuals of some species the leaves are entire, and on others as spiny as a leaf of the Holly-tree, or sometimes the leaves of the two forms appear side by side on the same branch. It is not surprising, therefore, that the student of trees is perplexed when he finds himself confronted with some of the California Oaks; or that every botanist who has paid attention to them has reached different conclusions with regard to the characters to be relied on to unite the different forms into specific groups.

A few of these western Oaks recall some of our familiar Oaks of the east; two species of the north may well be descended from the ancestor of our eastern White Oak and of our Post Oak; and the Black Oak of the western slopes of the Sierra Nevada, in foliage at least, is much like our common Quercitron Oak; but most of the California Oaks are of Mexican and Central American types. The most curious of them all to eastern eyes, save only the Tan Bark Oak (*Quercus densiflora*), which is almost as much a Chestnut as an Oak, and of an Asiatic rather than of an American race, is the Mountain Live Oak or Golden-leaved Oak (*Quercus chrysolepis*).

This is one of the largest of the California Oaks, and perhaps the most beautiful of them all; it is an evergreen tree, and the distinctive character to which it owes its Latin name is the golden tomentum, composed of a dense fuzz of jointed glandular hairs which usually covers the under surface of the leaves and the cups of the acorns, although

the amount of this covering and the brightness of its color vary greatly on different individuals; it is generally common, however, on the leaves while they are young, but gradually disappears, leaving the under surface whitish or bluish white.

In the cañons of the Coast-ranges, where the Golden-leaved Oak grows at its best, it is usually a tree forty to sixty feet in height, although individuals nearly a hundred feet tall may sometimes be found, with a short trunk two to four or rarely ten feet in diameter, dividing near the ground into great branches which, spreading at right angles, touch the soil with their extremities and form a mass of foliage sometimes a hundred and fifty feet across. The bark of the trunk and of the branches is ashy gray and covered with flaky scales. The leaves, like the young shoots, as they unfold are clothed with the golden pubescence, and make a charming contrast with the mature leaves of previous years. These are usually about two inches long, oblong, pointed, obtuse or slightly heart-shaped at the base, and usually entire on old trees, although on young and very vigorous trees, and especially on suckers, they are sinuate-toothed. They are thick, firm, bright and lustrous on the upper surface at first, although in time the bright green becomes more or less shaded with yellow. The male flowers, with eight to ten stamens and a five to seven-leaved perianth, are produced in short often branched catkins, while the female flowers are borne on short stalks, or are sessile on the branches. The acorn is oval, obtuse, half an inch to an inch and a half long, and is usually pubescent on the inner surface of the shell. Its base is enclosed in a cup covered with small appressed scales more or less hidden in the dense fulvous tomentum. The cup varies remarkably in shape and size, sometimes being hemispherical and sometimes saucer-shaped and very thick, with a broad thick rim.

In the fog-laden atmosphere of the valleys of the Coast-ranges *Quercus chrysolepis* develops into such a tree as we have tried to describe; more remote from the coast, and as it often grows scattered on high foot-hills, it becomes more symmetrical in the general outline of its narrow head, or at high elevations it is smaller, and on the slopes of the Sierra Nevada, where it is often found between three and eight thousand feet above the level of the sea, in Lower California and on the mountains of southern Arizona and of Sonora it is a small tree or often a little shrub with minute leaves and small acorns, but with the same general characters that serve to distinguish the great tree of the Coast-valleys. Some idea of the manner of growth of the mountain form of the tree and of the general appearance of the vegetation of the high slopes of the Sierra Nevada, may be obtained from the illustration which is published on page 127 of this issue, and which is made from a photograph taken by Dr. Wm. H. Rollins on the mountains overlooking the Yosemite Valley, although a series of illustrations will be needed to illustrate properly the appearance and manner of growth of this remarkable and interesting tree.

As a timber-tree *Quercus chrysolepis* is the most valuable broad-leaved tree of the California forests, although the trunk rarely produces logs long enough to manufacture into boards. The wood, however, which is very heavy, solid and tough, is well suited for wagon-wheels, agricultural implements and other tools, and the best trees, in spite of their inaccessibility, are now fast disappearing. It is probable, therefore, that in a few years, unless they can be protected in some way, all these great Oaks, the glory of California, worthy companions of the Sugar Pine and the Sequoias, and fit emblems of the Golden State, will have disappeared forever; for no one in California ever thinks of planting these trees or of protecting self-sown seedlings, which fall a prey to sheep and cattle, or are swept out of existence by the fires which year after year are burning ever-increasing gaps in the Pacific coast forests.

The California Oaks, when removed from their home, have not usually flourished. They are not hardy in the

east, where, perhaps, our summers are too moist for them; and in northern and central Europe they do not succeed, but in Australia, or in some part of the Mediterranean basin, perhaps some spot can be found where congenial conditions can be provided for these trees, and where, if they grow as they have grown in the California valleys, they will repay the care and labor needed to rear them.

Suitable Names for Country Places.

IN naming a country place there is great difficulty in hitting upon a title that shall be pleasing and suggestive without being hackneyed or savoring of sentimentality.

In an old country like England, where the language bears traces of Norse and Saxon and Roman occupation, there are a number of strong monosyllables descriptive of certain divisions of land that form effective combinations with more familiar words, or with a family name, for the designation of a country-seat or villa; so that their old titles seem particularly happy, and removed from the commonplace. Domesday Book contains a number of these ancient terms in its descriptions of the holdings of the people in the days of William the Conqueror. A toft was a grove of trees on a hill, a croft an enclosure, the meadow-lands were divided into garths and deals by great furrows plowed by eight yoke of oxen, the wavering course of which can still be recognized from some Yorkshire hill, as well as the wide sweeps made by them in turning the corners, showing the curiously unchanging character of English country life.

There were then, as now, moors, or heaths, of wide extent, wolds—which sometimes mean a wood, and again a hilly region devoid of timber, which may once have borne a forest on its rolling surface, of which only the name survives—and holms, which signify low, flat stretches of land near a stream, and also a river-islet. High ridges of land were known as rigs; isolated rocks, like towers, are still called tors; the groves were wealds, and the forest-clearings roydys; gate and forth, in Yorkshire, still mean a road. The old English name for a wild beast, *deor*, which in these combinations means a deer, survives in Darby, or Derby; in Darlands, also written Darelands and Deerlands, and in Dar-ton, which is found in old English as *deortun* (deer-park). A map of Derby, made in 1611, contains an emblematic drawing of a deer-park surrounded by a wooden fence, with a single deer in the middle.

Also, in such names as Goat's Cliffe, Kid Tor, Lamb Hill and Hart Hill linger pastoral reminiscences of old England; Gates head means the goat's hill, and probably Gad's hill is a corruption of the same word, while the palace of the Archbishop of Canterbury, Lambeth, bears record of a heath on which the lambs disported themselves before the town of London was built. A reminiscence of the Druids lingers in Seliok (blessed Oak), and a reminder of Christian zeal in Swinnock (burnt Oak), where the bishops cut down and burned these relics of heathen worship.

Throughout England the rural districts in their names bear traces of its history and its religions, of its early beliefs in fairies and giants, in Norns and sprites, and of the transfer of tradition to saints and the Virgin Mary, so that the titles of towns and fields and homesteads are an unfaillingly interesting study.

In our own geography we have reason to be grateful for such Indian names as have not been supplanted by honored English ones, or ugly inventions of our own, and some of these traces still linger in beautiful country-seats along the Hudson River, which are described by soft Algonquin syllables, as Algonac (hill and river), which is the name of a fine place at Newburgh. Canonchet is the Indian name of the Sprague place in Rhode Island; Noneguacut Farm of a Rhode Island sea-shore home, and Chamcook of an estate on Passamaquoddy Bay, formerly occupied by Mr. Wilson.

There is a pleasant set of names that we often find used both in England and this country, such as Hawkswood, Crow's-nest, Oaklands, Hillside, Bellevue, Eagleswood, and the like, which have become so hackneyed from frequent use that one hesitates to employ them, no matter how appropriate they may be to the surroundings.

Other names have associations which endear them to us, like Sunnyside, which Washington Irving has made famous; Edgewood, where Ik Marvel's farm continues to interest us; Idlewild, that Willis celebrated; Elmwood, where Lowell lived and died, so that we hesitate to apply them to any less well-known place. In fact, when one begins the search for a fresh and telling name he finds the crop pretty well harvested already.

The names of English seats have a dignified and unaffected air, sometimes bordering on harshness, often resembling the titles of towns rather than houses. Thus we have Drentham, the seat of the Duke of Sutherland; Woburn, of the Duke of Bedford; Bowood, of the Marquis of Lansdowne; Welbeck Abbey, the famous mansion of the Duke of Portland, celebrated for its underground rooms; Penshurst, the home of Sir Philip Sidney; Penrhyn, once the dwelling of a Cambrian prince; while Broadlands is associated with Lord Palmerston; Peshanger, with Lord Cowper, and in our own day Hughenden and Harwarden suggest Lord Beaconsfield and Mr. Gladstone of the ready axe.

In our southern states names were always given to plantations, and even to small estates, Jefferson's Monticello and Madison's Montpelier being as well known as Mount Vernon; and the names when given are accepted, as they are not apt to be in the north, where there is always a difficulty in making one's homestead wear a name after it has been christened. In spite of illuminated headings on the note-paper, places continue in popular parlance to be merely Smith's, Brown's or Robinson's, of blessed memory.

There are some good names of what Mr. Downing calls "gentlemen's seats" in the neighborhood of Philadelphia—Stenton, the old Logan place; Alverthorpe, the home of the late Joshua Francis Fisher; Wakefield and Brookwood, of other branches of the Fisher family; Belfield, the dwelling of the Wistars; Restalrig, the place of Mr. G. G. Logan; Aysgarth, of Mr. John Lambert. Barclay Hall was the name one Quaker gentleman gave to his home, in memory of Barclay of Ury, and Oxmead was chosen by another to designate his broad and fertile fields near Burlington, New Jersey. Champlost was so called in memory of a French town, where a former owner narrowly escaped death, and Butler Place was the property of Fanny Kemble's husband, and bears his family name.

People are fortunate when they find an old name that really belongs to the place they inhabit, as Dosoris does to Mr. Dana's island, it being the country contraction of the old *Dos uxoris* in the ancient deeds of the spot. Indian Hollow is another good name that bears an old record in New England, as does Hamlet Lodge, the residence of the late Dr. Alexander Vinton, while Christopher's Camp was the appropriate name of a Maryland farm-house; but such titles are scarce.

It has been suggested by Mr. Rutenber in his *Indian Tribes of Hudson's River*, that many of the Algonquin syllables would form melodious combinations of graceful significance in the naming of places. Thus we might have: Napeena, abounding in birds; Algansee, water of the plains; Iosco, water of light; Iénia, wanderer's rest; Shominac, grape-land; Tallula, leaping waters; Osségo, fair view; Biscoda, beautiful plain; Minoma, good water; Patósia, fair hill; Osio, fine view; Tario, beautiful rocks; Ackiana, good land; Acoma, rock water; Coio, beautiful falls. The syllable *io* signifying beautiful in the last five combinations.

The characteristics of a spot should largely influence the selection of its name, a soft and harmonious landscape calling for melodious syllables to express it, while a wild and rocky scene would find better expression in some rough guttural, some ending in *ough* or *orth*, which might convey severity or sternness in the landscape. There is a bleak and dreary sound in Cawdor, as of a spot haunted by ravens, while in Elsinore and Tantallon we catch the echo of the sea resounding in its hollow caves. Scotch names seem to harmonize with the landscape. Loughrigg, Glencairn, Argyll, Lochiel, savor of rocks and heather, while Stirling and Dumbarton, Crichtoun, Lennel and Montgomerie, have a soft suggestion of sunny stream and laughing brae in their smoother syllables, that lend themselves readily to music, which, however, even their longest and apparently most unwieldy names do at the will of that wonderful minstrel, who sings:

Hoot awa', lads, hoot awa',
Have ye heard how the Ridleys and Thirlwalls and a'
 With Willimondswick,
 And Hard riding Dick,
And Hughie of Hawdon, and Will o' the Wa'
Have set upon Albany Featherstonhaugh,
And taken his life at the Deadman's-shaw?

What a lilt there is in the very sound of the border lairds' dwellings; the song gallops like a bevy of moss troopers over the sod; one hears the measured rise and fall, the clink of hoofs, the jingle of bits, the rattle of reins, the rush of the lads as they sweep on in their fury.

The Scotch habit of naming a man from his acres has a distinct advantage by doing away with the monotony of Grahams and Gordons, Campbells and McIntyres, that would otherwise overwhelm the land of clans. But who thinks of Lochiel as

an estate? yet such it is, and its owner's name is Cameron, while James Hepburn's patronymic is forgotten in the better-known Castle of Bothwell.

Dunira, the seat of Sir David Dundas, we hear of in the poem of the Ettrick Shepherd,

Bonny Kilmeny ga'ed up the glen,
But 'twasna to meet Duneira's men;

while the castle of the Duke of Buccleuch becomes the background of the *Lay of the Last Minstrel*, where it is commemorated in that splendid martial opening,

Nine and twenty knights of fame
Hang their shields in Branksome Hall.

Tantallon, the stronghold of the Douglas, Artornish, where were the "rugged halls" of the Lord of the Isles, live in Scott's stirring verse with Roslin and Rokeby, Marwood Chase and Norham Castle, beside Netherby, Mingarry and Snowdown.

Firbeck is a good descriptive English name for a place, and so are Birkenbog and Netherlaw, which last belong to Sir Robert Abercrombie. Quiddenham and Skutterskelfe, Gwaynenog and Shillinglee are instances of indifference to euphony that we should hardly venture upon in this country.

Holnicate, Hennerton, Ravensdale, Tregothnan, Hackwood Park and Forglen House are all the homes of nobles or gentlefolk in England, and many others might be adduced for copy or example, though some combination with the old Saxon titles of holdings seems the most easily adapted to our needs.

Thorncroft is a good name for hedge-encircled grounds, Maplehurst for an enclosure with fine Maples, Birchwold for a house in the woods, Beechtoft for a hill crowned with these trees, Darhut for a lodge in the Adirondacks. Windycot sounds well for a sea-shore cottage, and Kineforth for a farm. One merry gentleman calls his hunting-lodge on top of a breezy hill Hitititi, which seems like Polynesian, but is pronounced with an English *iota*. Sorrowsikes is the gloomy title of the Tennant Place in Wensleydale, England; while Smyth's Folly is a commemorative term not bestowed by the owner himself.

A substantial volume might be filled with names already appropriated, but the most interesting field for research is in the Indian survivals, which I should be glad to receive from any one who could furnish them, and with them, if possible their signification.

Hingham, Mass.

M. C. Robbins.

Notes of a Summer Journey in Europe.—IX.

I HAD been advised to visit the famous Muskau Park, the masterwork of Prince Hermann von Pückler. Accordingly I went, and was not disappointed. As it was only four or five miles off the main railroad, between Berlin and that part of Silesia mentioned in the last number of these notes, it was an easy matter to stop over at Weisswasser, on the way back to Berlin, and take the short spur railroad to the little village, or town, of Muskau. It is seldom visited by strangers, although only three or four hours' ride from Berlin. The region all around is a most unpromising one for the creation of what has been called the best park in Germany. It is for the most part a sandy plain, which furnishes poor material for vegetable growth, or else the land is so low and flat that marsh-hay is the only harvest. Other large stretches are covered with a growth of Scotch Pine. The park, therefore, seems like an oasis in the midst of a comparative desert. The greater part of the site of the park itself was originally covered by swampy meadows or sandy plains, with no trees except a few old Oaks on some rising ground at a little distance from the River Neisse, which flows through the estate, while a few Lindens were growing near the village.

Prince Pückler carefully studied the peculiarities of each part of the ground before planting, and so laid it out as to obtain the best possible natural effects. It is designed in large, simple, but beautiful lines, appearing as if planted by nature in her best moods, and giving the feeling that any other arrangement would be out of place. Prince Pückler made nature his life-long study, and his whole style of landscape-design rests upon a clear understanding of it. He was regarded as eccentric, a character which has been attributed to many a genius, particularly to students of Nature. Goethe is recorded as having said, on leaving the Prince after a visit at Muskau, "Nature is the most grateful, if the most unfathomable, study, for she makes the man happy who will be so."

In his early travels in England, France and other countries Prince Pückler, no doubt, saw and noted much which was afterward of service when planting his estate.

It is perhaps from the schloss and other points on the western, or village, side of the park that the finest views of the best part of it are to be obtained. The arrangement of the specimens and groups of trees is so admirable that there is not a feature distracting or displeasing to the eye. Fresh vistas and landscape-pictures are brought out at every step or every visit, and roads and paths are so skillfully planned that their existence is unsuspected until they are stepped upon.

Most of the roads are so simply and naturally laid out, with due regard to the natural conformations of the land, that one wishes for a Prince Pückler in the designing of some recently made parks where roads often seem to be a main feature, where hills and great rocks have to be removed or mutilated and natural ponds filled in order to conform to lines traced on some chart, apparently without much reference to topography.

The banks of the river flowing through the estate, and of the artificial lakelets, are broken and hidden by appropriate trees, shrubs, reeds and grasses. Where different kinds of trees have been used in grouping they have been so carefully selected with regard to color and quality of foliage, that the whole makes a perfectly harmonious picture; and where shrubs are used about them to hide trunks and make an unbroken mass of verdure to the ground, the same thorough discrimination is shown. Specimens and groups of Lindens, Maples, Beeches, etc., have been used with charming effect, and the general absence of variegated or other unnaturally colored foliage is very pleasing. Two or three splendid specimens of the purple-leaved Beech do not look out of place. Sometimes three trees have been planted together, the trunks arising together at the ground, but afterward spreading apart, and a broad and handsome effect has been produced, the lower branches resting on the ground. The native White Oak (*Quercus pedunculata*) has chiefly been used in this way. For a number of years, during the planting of the most beautiful and interesting part of the park, large trees were brought from wherever they could be found in the surrounding country, in order to more speedily bring about old, park-like effects. When it is stated that some of these trees were fifty feet high when brought here, we have a slight idea of the tediousness and expensiveness of the work.

A large nursery was established in 1824, and it was then managed without regard to cost or income, as the first great aim was to raise plants for the estate and to introduce desirable species and varieties. To-day this nursery is a regular commercial establishment of 150 acres of thrifty-looking stock. Comparatively few of the plants propagated are now used on the park, and the present proprietor endeavors to make the nursery profitable.

Prince Pückler's enthusiasm led him to expenses beyond his means, and in 1847 he was obliged to sell his beautiful park to Prince Friedrich of the Netherlands, who, it is pleasant to know, carried on the work in much of the spirit of the designer. Prince Pückler died in 1871, and the Prince of the Netherlands in 1881, and the estate then passed into the hands of Count von Arnim, the present owner.

As notices of a general character occasionally appear regarding the Muskau Park, it may be of more interest to briefly note the condition of some of the trees and other plants which have been introduced here. Almost opposite the main entrance to the park is a very fine specimen of the Silver Linden (*Tilia argentea*), with a trunk fully fifteen feet in circumference. At the time of my visit (August 11th) it was in full bloom and giving forth a rich powerful fragrance. It is grafted, apparently on stock of the indigenous species of Linden, at some distance from the ground, and the stock is now considerably smaller in circumference than the trunk of the main tree. One or two other smaller specimens of the same species are to be seen. The marked discrepancy in size and color between the stock and cion, of course, destroys the beauty of the trunk, gives the trees a top-heavy appearance, and affords a warning against the use of poorly grafted ornamental or shade trees, unless the color of the bark of both stock and cion is known to harmonize and the rate of growth to be equal. Of course, where the point of grafting is below the surface of the ground, or even where branching begins, there is not the same objection against the use of dissimilar species as when the grafting is done midway on the stem. Fortunately, cases of this kind are rare in the Muskau Park. Grafted specimens of our Black Ash (*Fraxinus sambucifolia*) and of the Ohio Buckeye (*Æsculus glabra*), the latter on Horse-chestnut stock, are smaller than their stocks, while *Fraxinus pubescens* grafted on *F. excelsior* at several feet above ground has grown much faster than the stock, and the difference in the bark of the two species forms an unpleasing contrast.

Prince Pückler's enterprise secured for him quite an assort-

ment of some of the best of our hardy American deciduous trees. The Red Oak (*Q. rubra*) is here and in other parts of Germany many greatly valued and much planted as a shade tree, and it thrives admirably and grows very fast even on comparatively poor soils. A specimen of this species in the park has a trunk about four feet in diameter; a Black Oak (*Q. tinctoria*) is about three feet through, and there are fine examples of the Pin Oak (*Q. palustris*). Our annual fruited or White Oaks do not appear to thrive here like the three species mentioned, which belong to the biennial fruited or Black Oak-section. A specimen of the Red or River Birch (*Betula nigra*) has a trunk over two feet through; the Tulip-tree flourishes, and the Wild Black Cherry (*Prunus serotina*) grows to small timber size. The ubiquitous Locust (*Robinia Pseudacacia*) is seen in various parts of the park, and in differing soils. In some situations it has become like a weed, and I saw a small plantation of *Picea Sitchensis*, which was considered ruined, owing to the persistence with which Locust-suckers came up among the Spruces. Our Juneberry or Shadbush (*Amelanchier Canadensis*) is here a fair-sized tree, and has been planted in situations where its early summer bloom may make an effective feature in the landscape. There appears to be much interest in our Hickories in Germany, but there is frequent complaint that they do not thrive well. In good soil at Muskau, however, they seemed perfectly at home, and quite as vigorous as any I ever saw. Shagbarks (*Hicoria ovata*) forty or fifty feet high, Mockernuts (*H. alba*) forty feet high, and large Bitternuts (*H. minima*) were fruiting freely, and the new growths on the branches averaged six inches or more. Of our conifers the White Pine and *Taxodium* are among the best, and there are some very fine specimens of the latter.

Although many foreign trees have been introduced throughout the park, the skillful designer relied upon indigenous species in his most effective work and in the planting of woods. Native Oaks, Lindens, Beeches and Maples are largely employed, and the free use of the Hornbeam (*Carpinus Betulus*), with its light foliage, breaks the monotony which too many heavy-leaved species would produce. Groups of the native Alder (*A. glutinosa*) have been freely planted. This becomes a large tree, and a splendid specimen of a cut-leaved form was noted, which has a trunk nearly two feet in diameter, and has much of the aspect of a Red Oak in foliage and branching. Some good specimens of the so-called Crimean Linden (*Tilia dasystyla*) are to be found here. This is a tree of comparatively recent introduction into cultivation, and it gives promise of becoming valuable in street-planting. It is a very distinct species, being easily known from all others by its dark shining green foliage. For size and age and sturdy grandeur some native Oaks (*Quercus pedunculata*) are the pride of the estate. A number of these are from sixteen to eighteen feet in circumference; other individuals measure twenty-two and twenty-four feet, while the largest, known as "Hermann's Oak," is twenty-eight feet around at two or three feet from the ground, and is estimated to be over eight hundred years old.

The scientific as well as the æsthetic interest of those who planned and completed the park is shown in the arboretum which was planted about 1858 under the direction of E. Petzold, the park inspector, who was most deeply interested in the project. This arboretum comprised several hundred acres, most of the soil being sandy or rocky, although there were some fairly fertile small portions. During the past ten years it has been entirely neglected, and has become overgrown with Lichens, Heath (*Calluna*) and Broom (*Cytisus scoparius*), and haunted by deer, rabbits and other animals encouraged by sportsmen.

All the trees and shrubs were systematically arranged according to families and genera, and the species were thoroughly and distinctly labeled. A large number of these labels still stand, where not broken by roaming hoofs. They are neatly made of coarse earthenware, about an inch thick, with the lettering stamped in and painted black, and afterward glazed and fired. The length of the label is over a foot, the upper half neatly squared and margined, the lower tapering, to facilitate insertion in the ground. The catalogue number, scientific name, with the authority, the family and habitat are given. This gives an imperishable label, if not subjected to hard knocks. In arranging the specimens three individuals of a kind were commonly planted in a triangle; but a larger group was sometimes formed.

A walk through the arboretum now furnishes some interesting object-lessons in the behavior of some of the introduced plants under absolute neglect and in sterile soil. Most of them are dwarfed and stunted, and it is only a matter of a few years before they will disappear. Gray, lichen-covered specimens of *Viburnum dentatum*, *Myrica cerifera*, *Halesia*

tetraptera and others looked very forlorn, but *Clethra alnifolia* was flourishing and seemed quite at home. Our Wild Crab (*Pyrus coronaria*) was thriving quite as well as any member of the genus to which it belongs, but it was not fruiting.

In one or two places in Germany inquiries were made for the Rose Acacia (*Robinia hispida*) on its own roots instead of grafted. In this neglected arboretum it was found springing up spontaneously, over considerable ground, from spreading underground roots. These plants were slender and diminutive, appearing almost herbaceous by growing among the heath, which they hardly exceeded in height, but were freely bearing flowers.

Adjoining the park are the mineral baths of "Hermannsbad," which were developed and brought into notice by Prince Pückler, and which are annually visited by large numbers of people from the German cities.

Arnold Arboretum.

J. G. Jack.

Notes in the Woods.

ALTHOUGH I have been a farmer for years, I have never until lately owned any considerable stretch of woodland. But my "neck of woods" interests me now more than any other part of my farm-lands. It lies in a deep valley on both sides of the Clyde River, a stream fed by many springs, and passing through or contributed to by a number of small lakes of remarkable beauty. Its source is Island Pond (a name familiar to many as a station on the Grand Trunk Railway), and it has run nineteen of its twenty-one miles of length before entering Lake Memphremagog, when it becomes, for some hundred rods or so, my own particular property. This deep gorge, between one and two hundred feet below the level of the surrounding territory, is covered chiefly with Maples, constituting what is known as the "Sugar Place" of the farm. But there are also a goodly number of Beeches, Canoe Birches, Spruces, Hemlocks, Firs, Poplars, Ashes, Pines, and by the river-banks dense thickets of *Arbor-vitæ* in sizes from two feet in diameter down to those just right for hop-poles and bean-poles. The narrowness and depth of the valley causes all these trees to run up very straight and tall, with but a small amount of top, many being as much as forty feet from the ground to their lower limbs. All among them copious springs burst forth, one of the largest furnishing water to actuate a hydraulic ram which supplies the buildings of the farm with the purest and softest water.

One of the first things that attracted my attention in regard to the trees of this valley or ravine was that a large proportion of those of much size are rotten at the heart or hollow. This is noticed in more than one-half the logs that are drawn up to the house for firing. Not many of the Spruces or Firs are thus affected; but I was astonished to note that what are called our most durable timber-trees, used everywhere for fence-posts, the *Arbor-vitæ*, become thus decayed by the time they are a foot through. I had thought that perhaps this might be due to the severity of the climate; but a visit to the Aroostook country, in Maine (whose southern extremity is one hundred miles north of my latitude), showed me, in its beautiful and perfectly sound *Arbor-vitæ* timber, that this could hardly be true. I have since noticed that a very large proportion of the *Arbor-vitæ* logs brought to our mills to be sawn into shingles, or sold for posts, are rotten at heart.

In my experience the Firs make a better and more lasting roof-covering than the Cedars. Some twenty years ago, in building a house upon my old "home place," on the Memphremagog shore, being desirous to avoid the Cedar taste in cistern-water I had the part of the roof from which the water was taken covered with Fir shingles, the remainder being covered with the best cedar to be had. Sixteen years later, when re-shingling became necessary, the Fir shingles were found to be considerably sounder than the others.

The Maples interest me greatly. Not only the Sugar Maple, but the Red and White Maples abound, covering both flanks of the valley above the wetter portions near the river. Some months ago I mentioned that we had a sort of Maple which neighboring farmers say is not the White Maple, though they have no other name for it, and it looks to me like a White Maple. The sap of this tree acts quickly and strongly upon the iron spouts used to conduct the sap into the buckets set to catch it, and makes the syrup quite black and unfit for sugar. One can notice the quickness of its attack upon the iron as it trickles over it; but this appears only with a few trees, the sap of other White Maples not showing this quality. The only difference I can note between the trees which do and those which do not have this peculiarity is a darker bark on the former.

I cannot distinguish even the slight difference I have referred to, except in the larger trees, and I have been waiting until another season to notice, if possible, any difference in the blooming time or anything else of a specializing character.

I was struck by a short notice in the *Boston Daily Traveler*, of February 20th, relating to Indian basket-makers in Maine. In this notice it was said, speaking of the bright colors that were secured from the woods by these sylvan workmen, that "Alder is steeped for pale red; White Birch bark for bright red; Cedar-boughs for green; Sumach for yellow; black comes from White Maple bark. A light solution of Maple, however, shows purple instead of black." It may require the skill of a chemist, along with that of the botanist, to get to the bottom of this little problem. It seems quite probable that this blackening of the sap by contact with the iron spouts occurs only in the case of a few out of many of the trees supposed to be all White Maples. One old farmer said he thought these might be a cross between either the Red or the Sugar Maple with the White—but he was no botanist. Is it not possible that this peculiar tree may be a hybrid between the Red and White Maples?

Housetop Gardens.

THE effort of the directors of the Columbian Horticultural Exhibition to show roof gardens on an extensive scale is a step in the right direction. City life cannot only be made more comfortable by a supply of fresh flowers and vegetables but it can secure considerable of the greenness and aroma of the country. The present style of building is, with slight adjustments, well-adapted to this. I have seen the roof of a house and wing utilized with a lean-to glass roof, without any heat beyond that obtained by an open door into the upper hall. But, if needed, portable heaters could be used. In one case a friend has conducted steam pipes from his furnace into his roof-room, where he makes a specialty of growing Cacti. Housetops, when flat, can be covered with glass and used for a great variety of fruits, flowers and vegetables. This also can be heated in winter, mainly by the hot air that is wasted in the house. Better yet, it is carbon-laden air that goes up; and is ready to be used by vegetation. As a matter of health, the roof garden has decided advantages, provided it be wisely constructed. I know a dweller in a western city who grows his tomatoes and cucumbers in half-barrels and tubs filled with rich soil. His garden is on a second story roof, and a door opens into an upper hall. His purpose is not so much a winter garden as a summer garden. Besides vines, he grows an abundance of lettuce and radishes, and even gooseberries and currants. Probably most cultivators would prefer to experiment with grapes, figs, and perhaps dwarf oranges. This is a matter of taste. The roof garden may be made convenient for almost any sort of vegetable growth not too heavy for the framework of the house. I have seen pumpkins grown to perfection on a New York roof, and tubs of charming evergreens, six or eight feet high. The growth of flowers on a roof may be conducted in connection with fruit and vegetable growing, or alone, and I have had some choice bouquets from such gardens.

I have spoken of roof gardens with glass overhead. This is but one, and the more expensive method of establishing such culture. The ordinary garden has no cover, and it may be as well established on a housetop as in the back yard. The only thing necessary is to make the weight proportioned to the timbers of the house. The London *Horticultural Times* is urging this sort of summer garden on the people of that metropolis. It proposes an iron spiral staircase ascending from the upper floor through a turret leading to a plateau where the growth is established, and seats are provided for rest and pleasure. Protect the roof with a strong parapet and then lay out your garden as you please. The same London journal proposes as follows: "At the back, partly or right across, one could erect a simple and cheap little glass house; or it could stand exactly in the centre. Around all the sides of the parapet and the glass house one, two or even three rows of pots of various sizes could be placed, in some of which the seeds of plants or flowers could be grown, and the glass house could be utilized for the production of such seeds and bulbs as required, or are improved by being raised under cover or in heat." But this at once turns the open garden into a matter of care and expense. I should prefer simply to use large tubs or boxes, and grow such plants as require only sunshine, air and water. The cultivation would be simple. In many cases water could be carried to the roof as it is to the

rooms below. A stout roof could be built that might sustain a garden spread over a part or even the whole of the surface, with soil deep enough for vegetables, vines and flowers. Here is a chance for even more taste and ornament than in an ordinary garden. I think weeds would be less troublesome, and insects of the worst sort would be quite shut out. What a chance for a Rose gardener, and for Lilies and Gladioli. All the common flowers like Wallflowers, *Tropæolum*, Mignonette, Petunias, and, above all, Geraniums would readily take to such a home.

As an economical measure the roof garden may constitute a noteworthy feature of future city life. The poorer families, unable to command a rod square of area below, may grow some of the most needful provisions above. Oriental nations have for ages utilized housetops for all sorts of purposes. Not only kings, but the populace eat, sleep and garden on the roofs. The suburbs of American cities need nothing of the kind; but the city houses do. The tenement-house would be easily robbed of some of its terror if the roof were furnished for sleeping; and with a few tubs of trees and common flowers. So far we have looked more to the glory of increasing the size of cities than to the increase of their attendant comforts. Economy and health and pleasure can all be combined in roof gardening.

But the most practicable immediate use of the roof garden is for the families of professional men and others who long for some contact with growing things, a bit of nature, wild or tame, all to themselves. Most women would enjoy such a resort, and the homely comfort of dabbling in dirt.

The experiment at Chicago is a happy thought. The whole subject can be studied. I hope the effort to produce grand effects will not predominate to the exclusion of the wants of those who can only work in a humble way. It is plain poor men's and poor women's problem in one sense. It is the flower-pot multiplied and put to practical purposes. And if a single window-plant may help to brighten the life of the city poor, roof gardening may help considerably to relieve some of the trying conditions of city life.

Clinton, N. Y.

E. P. Powell.

Roses.

AS the sunshine strengthens with the approach of spring more ventilation will be needed in the Rose-house, but low temperature with high winds often prevail in March, and if these cold draughts are permitted to circulate among the Roses an attack of mildew will inevitably follow. The heating apparatus also requires close attention, for while the nights continue cold, the days are often warm, and consequently the temperature under glass may change rapidly. It is a safe rule to begin ventilating as soon as the temperature in the Rose-house reaches seventy degrees, and to increase it gradually as may be necessary.

All watering and syringing should still be done early in the day to prevent excessive moisture during the night, though syringing may be done with more freedom now than a month earlier, and the water should be applied with sufficient force to prevent red spider from getting a foothold, since this pest is likely to appear at this season. Liquid manure is generally beneficial now, but is best applied in moderation, and only the clear liquid should be used after the solid matter has settled to the bottom of the tub or tank. Much injury is done by applying thick manure-water, from the fact that the sediment forms a comparatively air-tight coating on the surface of the soil and prevents its proper aeration. Old-established plants will, of course, assimilate more strong food than those less firmly rooted, but it is better to err on the side of moderation than of excess. Of course, it is understood that proper soil has been used in the first place for filling the beds.

Early Rose-cuttings will be rooted before this, and it is well to pot them off before the roots grow to any great length in the cutting-bed, for there will be less liability of breaking the roots in the operation of potting while the roots are short, and the young plants will become established much more quickly than those whose roots have been crippled. Young Roses must not be permitted to starve in very small pots if healthy and strong plants are desired for summer planting, for under such treatment little more than a stunted growth can ever be hoped for.

At this season some good cuttings may be secured from hybrids that have been forced early, and from which the crop of bloom has been cut. The sooner such cuttings are put in the better, in order to furnish young stock for next season's crop. Firm shoots with clean and healthy foliage only should be selected for this purpose, and with reasonable care they will soon root.

The decree of fashion seems to have been somewhat against the old favorite, La France, this season, and even more so against its offspring, Duchess of Albany. This is perhaps less surprising in the latter instance than the former, for while the Duchess of Albany is very handsome when in perfect condition, yet many of its flowers are too dull and undecided in color to appeal to the fastidious buyer, and as soon as its novelty had worn off its popularity began to wane also. Catherine Mermet has been much more in demand, the lighter shade of pink being preferred, and there are certainly few Roses that can compare with this one for beauty of form and delicacy of coloring when well grown. Meteor, too, has been gaining in popularity, and with some growers proves a profitable variety, while in other localities little success has been found with it. Still another sport from Mermet is to be disseminated soon, and from the description it seems to greatly resemble Waban, and possibly may be identical with it, for it is not extraordinary for the same freak to occur in two localities. This actually happened in the case of The Bride.

Holmesburg, Pa.

W. H. Taplin.

Bulbous Plants in Winter.

IN the greenhouse January and February are very satisfactory months. The crops of flowers are abundant, and there is not too much pressing work. The propagating season has not fairly begun, and, besides routine work and entomological studies, there is little to do beyond watching the expanding flowers.

In any greenhouse room is very valuable, and in a small one it is only by the exercise of considerable management and foresight that the house is kept well furnished with flowers at all seasons. "Plants which are always in bloom with showy flowers" are still rather scarce, and only a certain proportion of a small house should be occupied by permanent herbaceous plants—these to include, of course, such decorative plants as may be required for foliage effects or may interest the grower. Many amateurs are interested in special species and devote their entire attention to them; but where it is simply desired to secure a constant succession of flowers at all seasons it will be found that a well-selected stock of bulbous plants are the amateur's best reliance. With a good supply of these the smallest house may be kept always gay, reserve stock being brought forward at the proper season. After flowering they can be put in an inconspicuous place to open or rest, and be replaced by others.

The variety of bulbs, corms and rhizomes is endless, giving one an opportunity to select a good supply of those pleasing to one's particular taste. The common bulbs, which are needed in some quantity and are repotted each season, are best grown in short pots or Lily-pans, those of eight inches in diameter being a useful size, and if of standard pattern can be snugly packed away when not in use. These are not very conspicuous, and hold sufficient earth for most bulbs. They are much preferable to ordinary deep pots of the same diameter, which are too prominent, and to flats, which are very difficult to place on an ordinary greenhouse-bench and cannot be taken into living-rooms. In these pots the bulbs should be planted thickly for effect when in flower, and allowed to make root in proper quarters, which will vary according to the species. Fortunately, some of the commonest, cheapest bulbs are the most satisfactory, and it is possible to have a succession through the winter with very slight expense. Roman Hyacinths are perhaps the most satisfactory winter-bulb for all purposes, being free, graceful, not too fragrant, and to be had at any desired time; the rose and blue are pleasing, but not as useful as the white. The Dutch Hyacinths are popular flowers easily grown, but one usually apologizes to himself as their lumpy flowers appear, for a plant not pleasing both in form and color is never quite satisfying. Their mass of color is useful, however, in brightening up dark corners. A few pans of Tulips, especially of the light colors, should always be grown, but will need care in not bringing on too quickly. Freesias are deservedly popular and never in too great supply, though the bulbs increase so freely. There does not seem to be any difficulty in growing this desirable plant in a cool greenhouse. It is well to try to select bulbs giving the purest white flowers, which are the most pleasing. Allium Neapolitanum is one of the most useful winter-blooming bulbous plants. The bulbs force readily, and the cymes, of pure white flowers, are very attractive. Unlike other varieties of this family, this has no objectionable odor.

Of the Narcissi, the Paper Whites and bunch-flowered kinds, generally, are so charming that one hesitates to add that they are also malodorous and impossible flowers for cutting. A pan of *N. Bulbocodium*, or Hoop-petticoat Daffodils, is

Fig. 20.—The Golden-kevel Oak (*Quercus chrysolepis*) on the high Sierra, Nevada.—See page 121.

very charming, and, in fact, one can scarcely go amiss in growing any of the varieties. There is such a wealth of material in the family which may be had at a low price that it does not seem worth while to risk choice varieties in the warm house, where they are often neglected after flowering. Of the double varieties the Trumpets or Von Sions, and the incomparabilis, Codlins and Cream (albus plenus sulphureus) are the best. Of the latter section there are many very inferior varieties on the market to be avoided. The large single Trumpet, or Ajax Narcissi, are the most pleasing. Of the bicolors Horsfield's is the best, but being still high-priced a substitute may be found in *N. bicolor præcox*, the Italian bulbs of which are very cheap, and while not all true to type as sent out, are very satisfactory. Mr. A. Blanc kindly secured for me a bag of these as collected, which were very interesting, as they were all handsome forms with considerable variation in coloring. No collection is complete without a supply of *Cyclamens*, while among the *Amaryllids*, *Crinums*, *Hippeastrums*, *Nerines*, *Pancretiums* may be found many handsome flowers. If somewhat cool quarters can be found, the Cape bulbs open a wide field of interesting things which generally have to be brought on slowly. Pans of *Lachenalias* are quaintly beautiful, as later on are *Ixias*. *Gladioli* species are to be had in many forms, two of the best being *G. Colvilli* (The Bride), a fine white variety, and *G. tristis sulphureus*, a yellow kind. The bulbous *Irises* are choice things, but rather fugacious, *Iris reticulata*, however, being much more lasting than *I. Pavonia* or *I. maricoides*, which latter is a quaint little plant just now in flower. Before the last of the winter-flowering bulbs disappear and the fires go out summer bloomers, like the *Gesnerias* and *Begonias*, will show signs of life and may be brought forward for succession.

Elizabeth, N. J.

J. N. Gerard.

Sowing Beets and Radishes.

MANY people at the north delay sowing Beets and Radishes until rather late, for fear of frost. These vegetables will endure much cold, and it is easy to get them early with little trouble. In this latitude we sow Radishes at any time after the 1st of February, and Beets after the middle of the month, though we are apt to have returns of frost all the month. The first requisite for getting early Beets and Radishes is a mellow, deep and very rich soil. A heavy application of an ammoniated fertilizer is preferable to stable manure, as it makes smoother roots. Get the soil on a warm border ready as early as it is possible to work it in good condition. Sow the seed in rows rather thinly. Seed of the scarlet Turnip Radish can be sown in same row with the Beets if space is limited, for they mature so quickly that they can be pulled out of the way by the time the Beets want all the space. Now have at hand a quantity of straw; good, long, straight rye-straw is best. Cover the bed with straw on frosty nights, but expose it to full sunshine in the daytime. Beets will endure quite a sharp hoar-frost after they are fully up above ground, but if caught by frost just as they are coming through they are very easily hurt. Radishes will endure much harder frost. But the straw cover will ward off any frost above twenty degrees, and enable one to get his beets and radishes much earlier than his neighbor who waits till frost is gone. Of course, any one who has a cold frame and some sashes can get his Radishes and start his Beets early; but I make this note for the benefit of the larger number who use no glass. The Egyptian Beet is a favorite of market-men on account of its small top, but it is of poor quality. Eclipse is better, but for those who prefer quality to looks, and who do not imagine a beet is better because dark red, I would recommend the old Bassam. It is as early as any and of better quality. Its big top is the only objection, though some dislike its light color. For a very early Radish the Scarlet Turnip is as good as any, but some Long Scarlet Short Top and some of Beckert's Chartier should be sown at the same time. The Chartier is good as soon as it is large enough to pull, and keeps on growing to a very large size before it becomes pithy.

Raleigh, N. C.

W. F. Massey.

Brodiaea (Triteleia) uniflora.—This plant was introduced into British gardens from South America about sixty years ago. It is perfectly hardy in England, and is said to be equally hardy in our eastern states, though I have never seen it out-of-doors here. Under pot-cultivation, however, it is excellent, and it is now in full bloom. It is a dwarf bulbous plant of the Lily family, forming dense masses of linear, pale green foliage, from which emerge the long, slender, erect scapes, each bearing a single starry blossom about an inch and a half in diameter, and of a deep lilac color when it first opens out, turning to pure white as it grows older. The flowers are produced

very freely during the latter months of winter and in early spring, and the plant is then strikingly beautiful. It is a first-rate subject for the window-garden, and thrives luxuriantly in ordinary soil provided it has a full supply of water while growing. Repotting is not often necessary, unless the drainage is faulty, but an annual top-dressing late in fall, before growth commences, is beneficial. The bulbs should have complete rest, that is, they should be totally deprived of water during the dormant period, and they will be most effective when closely planted in wide pans, where they will make a large and compact display of leaves and flowers. The only objectionable quality of the plant is its offensive garlic-like odor. This, however, is not perceptible unless some portion of it is bruised; the flowers themselves give off a faint sweet fragrance under ordinary conditions. Several varieties of this *Brodiaea*—or, as it has been generally called, *Triteleia*—are said to exist, but I have never been able to secure any of them. Certain variations are represented in the books, but they are probably unusual.

Cambridge, Mass.

M. Barker.

Crandall's Currant.—I have discovered a good use for this plant. With me it is a failure as a fruit-plant; it is, in fact, only a moderately good variety of *Ribes Missouriensis*. But it can be forced for winter flowers to great advantage. Its dwarfish, drooping, compact form of growth makes it adaptable to pots, and it grows with so little care and blooms so freely that I am inclined to place it at the head of the shrubs which can be forced for common home use. Small plants bloom finely, and the flowers are as sweet as they are beautiful.

Clinton, N. Y.

E. P. P.

Orchid Notes.

Orchids at North Easton, Massachusetts.

SO many unique and distinct varieties have been added by Mr. F. L. Ames to his collection that the visitor at any season will find something of interest in bloom.

In the large *Cattleya*-house are now to be seen well-grown specimens of the white *Cœlogyne cristata* covered with its snowy blossoms, besides specimens of the ordinary form in pans three feet across, and the true *St. Albans* variety of *C. cristata maxima* with over one hundred flowers. The *Lælias* of the *Anceps* type are showing well this season. A superb example of the variety *Stella* had twenty-two spikes carrying seventy-five perfect blossoms, and one of the variety *Sanderiana* had fourteen strong spikes. Mr. Wm. Robinson, the gardener here, gives plants of this section a long rest after flowering, with ample light and air while growing. *L. anceps Schrœderæ*, a pretty and very rare form, carried six fine blooms, its round petals being tipped with a fine magenta-purple, the lobes of the lip a rich purple, the front a dark velvety purple, with a prominent orange disk. Dawson's variety and Williams' variety are represented by first-rate plants, while among the red forms *L. anceps Winneana* was the finest, although other good ones like *L. anceps Scottiana*, a very rich dark-colored form, are just out of bloom. Of course, there are masses of the typical *L. anceps*, many of them distinct in character and remarkable as specimens. Mention should be made of the variety *Percivaliana*, which was represented by several fine plants.

Among the hybrids *Lælia-Cattleya Hippolyta* was flowering, with three soft yellow blossoms, each with a rosy-veined lip. This is a charming plant obtained by crossing *L. cinnabarina* with *Cattleya Mossiæ*. The pretty *L. flammea*, another very attractive hybrid between *L. Pilcherii* and *L. cinnabarina*, bears three spikes carrying nine handsome buff-yellow blossoms with lips of bright purple.

Some of the finest *Cattleyas* have finished flowering; but among the forms of *C. Trianae* in bloom was a plant of the true variety, *Leeana*, obtained from the Lee collection, which had three spikes. The enormous flowers have increased much in size since it first bloomed; its broad sepals and round petals, together with the bold purple lip, make a striking display. The variety *Backhousiana* is well flowered, and is readily distinguished by its broad blotched petals and richly colored lip.

Dendrobiums here are great favorites, and among the many in bloom is the pretty *D. Cybele*, a charming hybrid between *D. Findlayanum* and *D. nobile*, having white and rosy-tipped sepals and petals, lip white, with a suffusion of orange-yellow surrounding a purple blotch in the throat. *D. Aspasia*, an elegant hybrid between *D. Wardianum* and *D. aureum*, carries fourteen flowers. A profusion of delicate white and purple blossoms is to be seen on a well-grown plant of *D. euosium leucopterum*. There are two forms of this, but the plant here

noted is the finest. Over one hundred flowers of *D. Schneiderianum* make a mass of white golden yellow and purple, which proves it one of the most striking of hybrid *Dendrobiums*. It is of easy culture and quickly makes a specimen. Varieties of *D. nobile* were abundant, among them many plants of Cooksoni, the true *Nobilium*, and *Arnoldianum*, with its distinct broad purple stripe on the lower sepals. Schröder's variety of *D. Wardianum* bears to the type the same relation which the variety *nobilium* does to *D. nobile*, and its flower is strikingly beautiful and rich in color. The rare *D. MacFarlanei* shows fine clusters of its peculiar white blossoms, and *D. micans*, a hybrid between *D. Wardianum* and *D. lituiflorum*, bears masses of flowers. The hybrid *D. chrysodiscus*, *D. Goldei*, from Australia, and many plants of *D. Phalænopsis Schröderianum* are all noteworthy, especially a rich-colored form of the latter, which is much admired here. In this house is a group of choice *Cypripediums* in bloom, among them the hybrid *C. Calypso*, Low's variety of *C. villosum*, *C. nitens*, *C. Godseffianum*, *C. Petri*, *C. Niobe*, *C. ænanthum superbum*, *C. Measuresianum*, *C. Aylingii* and *C. leuchorhodum*—all in admirable condition and many of them noble specimens.

In another house four hundred flowers of *Odontoglossum Pescatorei* and the same number of *O. Alexandræ* make a brave show, and in the same house are quantities of *Cœlogyne cristata* and its variety *Lemoniana*. The most remarkable Orchid in the whole collection is here, the rare *Miltonopsis Bleui splendens*, a most beautiful hybrid, between *Miltonia vexillaria* and *M. Roezli*. It has two spikes of blossoms, which measure individually four inches across. The petals at the base are suffused with rosy purple, and the centre of the flower resembles a reversed coronet in fine bronzy purple. *Zygo-Colax Veitchii*, another interesting hybrid, shows sixteen flowers, with sepals and petals lemon-green, profusely spotted with blackish purple. Several plants of the white *Lycaste Skinneri* were flowering, and included a fine form named *Chantini*, with flowers of remarkable size.

Among other choice *Odontoglossums*, a first-rate plant of the variety *Dellense* of *O. tripudians*, carried a dozen of its yellow and chocolate spotted flowers; the rare *O. Pescatorei excellens* shows as many more. *Candidulum*, a white-flowered variety of *O. nebulosum*, is opening large white blooms with an orange-yellow crest; a distinct form of *O. ramosissimum*, named *Xanthinum*, is beautifully decorated with yellow and violet spotted flowers. Here, too, are the rare *O. Leeanum* and *O. Chestertoni*, while *O. Rossii* is represented in great variety and abundance.

Masdevallias delight in the cool moist corner allotted to them in this house. Here are several distinct hybrids, including *M. Measuresiana*, with white and pink blossoms; *M. Hincksiana*, with yellow flowers when first expanded, becoming paler in the centre with age; *M. Courtauldiana*, with blossoms of a soft rose color with yellow tails, and a new one, obtained by crossing *M. ignea rubescens* with *M. Lindenii*. The flowers of this hybrid are as large as the last-named, lilac in color, with the conspicuous stripes of *M. ignea*.

There is no need of specifying any other individual plants, although scores are to be seen here which would add materially to the value of any collection in the world. Many of the plants are matchless specimens; all are thrifty and happy, and bear witness to the exceptional care and skill with which they are managed.

New York.

A. Dimmock.

Orchids in Flower in New York City.

SEVERAL interesting plants are now flowering in the collection of Mr. Hicks Arnold, in Eighty-fourth Street, and at this dull season they are doubly welcome. It would be difficult to find elsewhere such a variety of Orchids in one structure, many of them ranked among the stove Orchids, thriving so vigorously, and attaining such dimensions, in so short a time. Very little shading is used here. The *Cypripediums* are grouped on the north side of the house, and produce annually a rich display of bloom. The *Cattleyas*, *Lælias*, *Dendrobiums*, *Oncidium*s, etc., receive the brightest position where air is admitted in abundance during their period of active growth.

At this season the *Cattleyas* form a leading feature, especially those of the *Trianae* class, among which are many elegant varieties. One of these is strikingly beautiful, having flowers measuring eight inches across, with a broad, open, intense purple lip, finely fringed. Here also is a true albino form, with snow-white flowers and orange throat. There are many so-called *Albas*, which, on close examination, show traces of pink; but the variety here is noted for its purity.

Lælia cinnabarina is flowering well, and so is a fine specimen of the true *Dendrobium crassinode album*, and the pretty *Lycaste Youngii*, a charming form of *L. Skinneri*, with salmon-colored flowers.

Dendrobium luteolum reminds one in color of the English Primrose, and near it is a fine specimen of *D. nobile Arnoldianum*. This is the largest plant of the variety in cultivation. Its blossoms are quite distinct, with a broad dark purple stripe on the basal half of the lower sepals, the lip being furnished with a very rich maroon centre, and the whole flower showing the same rich color as is found in *D. nobile nobilium*. Hill's variety of *Lælia anceps*, and near it a fine example of *Spathoglottis Kimballiana*, its golden yellow blossoms greatly resembling a *Phalænopsis*, are both well flowered. *D. dicuphum*, a rare plant from Australia, here shows elegant sprays of white flowers.

In the centre of the house is a fine specimen of *Ansellia Africana* carrying a spike of over one hundred blossoms, and the now popular *Dendrobium Phalænopsis Schröderianum* fully justifies all that has been written in its praise. One spike had produced seventeen elegant flowers, which were large and flat, and fine rosy purple, with a lip of intense purple. They are arranged gracefully on a long stem. The plants here receive as much light as possible, and are growing freely suspended from the roof. One of the finest Orchids in the whole collection is a specimen of the rare *Phajus Cooksonii*, a beautiful hybrid obtained by crossing *P. Wallichii* with *P. tuberosus*. This season it has produced on two spikes twenty-six perfect flowers, which are light bronze in color, the lip yellow, with numerous purple markings running the full extent of the throat.

The *Phalænopses* are just past flowering, but the ivory-white blossoms of *P. tetraspis* and the cream-yellow flowers of the rare *P. Micholitzii* still remain. *Vanda teres* and dozens of *Lycastes* and *Oncidium*s make a very attractive show. Among the *Cypripediums* is a specimen of *C. Schröderæ splendens*, showing three strong spikes of richly colored blossoms; the pretty *C. microchilum*, with an unusually large pouch; *C. Hera*, a bold-flowered hybrid; several plants of *C. Lathamianum*, a cross between *C. villosum* and *L. Spicerianum*, are flowering finely. Here, too, are *C. nitens*, the pretty *C. Schlimii*, several fine specimens of *C. callosum*, a handsome specimen of *C. grande*, and the rare hybrid *C. macropterum*, one of the best in the group, bearing its handsome marked blossoms on a long stem. Other noteworthy *Cypripediums* in flower are *C. Petri*, Smith's variety of *C. Dayanum*, the beautiful hybrid *C. radiosum*, its broad dorsal sepal suffused with numerous lines of rosy purple; *C. euryandrum*, with five spikes; *C. Sedenii candidulum*, with four spikes; *C. vernixium*; several distinct forms of *C. insigne*, and a striking form of *C. Boxallii*. *C. villosum* is abundantly represented, while a great variety still promise flowers, and for several weeks to come there will be plants in bloom to interest all lovers of this fascinating genus.

New York.

Correspondence.

A Small Conservatory.

To the Editor of GARDEN AND FOREST:

Sir,—I have a small conservatory without roof-light and not reached by the sun till after one o'clock. The heat is obtained from adjoining rooms, and in cold days the temperature often falls below sixty degrees, and well below fifty degrees at night. Still, the collection is now in a fairly thrifty condition, and some plants are flourishing.

A conservatory, with no greenhouse to draw from and with other drawbacks to contend with, must be carefully managed to succeed, and this letter is written, in part, to draw out experience from others, who may have solved problems that I have not. The first mistake likely to be made, supposing the plants to be well potted and thrifty, is to leave them out in the fall till they have suffered from cold weather. They should be brought inside before chilly nights come on, especially *Begonias* and other tender sorts, and the windows of the house should remain open as long as the weather permits. The flowers and often the leaves of many species will drop if brought in late and denied fresh air.

December and January are the trying months for winter-growing plants. February, even if cold and cloudy, affords many more hours of daylight than either of the two months preceding, and March is sure to be partly warm and sunny.

Set all tender plants on the upper shelves and away from the cold, exposed corner of the conservatory, and place the hardiest ones near the floor. Many desirable species will thrive on low

shelves where the glass is nightly covered with frost in severe weather. For the necessary moisture an oil-stove with a single five-inch burner will keep a half-gallon of water boiling any desired length of time, and the oil used is very little. Sprinkle the plants only when this added warmth and moisture are present. The evaporation of water from the leaves always cools them a good deal, and it will chill them if the room is cold and dry enough to make evaporation rapid.

Give outdoor air as often as safe, letting it come in through another room if possible. This rule is always insisted on, but it is too seldom followed. When a plant stops growing encourage it in taking a season of rest, by light watering, if that is thought to be the reason for inaction, but restore, if possible, the lost condition necessary to vigorous growth where rest is not thought to be needed.

From lack of heat, and in a less degree of light, I have been obliged to neglect this point somewhat, yet I do not think repotting is resorted to soon enough, generally, in cases of failing vitality. A large vigorous Leopard-plant (*Farfugium grande*), which thrives on the lower shelf, requires, like all of its species, copious waterings, but after a season without repotting it droops very soon after watering. It is then taken out of the pot and every particle of soil washed from the roots by agitating it in a pail of water. A careful repotting in new strong soil will completely restore it. Most plants should be occasionally repotted in the same merciful way.

Now as to plants that succeed variously in the conservatory described. It is not quite warm enough for *Abutilons*. The three varieties in the collection grow quite well, but they are not very stocky and most of the buds drop off. They are now budded again, and will blossom if the weather is not too severe. *Begonias* generally require more heat than I can give them. Of about fifteen species several drop their leaves badly, and only *B. carnea* and the round-leaved species really thrive, though *B. metallica* has done fairly well. No conservatory should be without *B. carnea*. It is perfectly at home there, and it blossoms in December, when flowers are scarce. It may not be generally known that this *Begonia*, if placed in a cool window when in full bloom, will retain its blossoms all winter, while if kept in a warm room they will soon fall. Its habits are entirely different from any other *Begonia* that I am acquainted with. There is not heat enough for *B. Weltoniensis* and its class. As they do not blossom in winter, they would be put into the cellar but for the fact that they often die there.

Of course, *Orchids* are out of the question in a cool conservatory, and *Roses*, *Carnations* and *Violets* have not succeeded well with me. I am puzzled to know why *Geraniums* and *Nasturtiums* have not done better. The former stand almost still, and the latter grow so spindling that flowering is out of the question. Both are wintered for early-bedding plants merely. Even a badly attenuated *Nasturtium* will blossom out-of-doors ahead of plants direct from seed.

Fuchsias thrive in cool conservatories, but seldom flower till winter is about gone. I find *Storm King* too slender, indoors or out, but I have another and very vigorous variety with blossoms almost identical with those of that variety, so that its waywardness is not greatly regretted. Few plants repay wintering better than *Fuchsias*, for they can be rapidly multiplied by cuttings, and thrive in summer in almost entire shade.

Most foliage plants that do not form succulent stems do well in imperfect heat. The *Palms*, particularly *Kentia*, *Latania* and *Cocos*, the *Rubber-plant* (*Ficus elastica*), *Dracæna*, *Pandanus*, *Yucca*, etc., should be given prominence. Their only fault is that they often become too large for a small conservatory if many, and especially small plants are desired. They all thrive in an ordinary cool window. The true cultivator is always putting in small plants with slender lease of life, on which to experiment, with hope of nursing them into a flourishing state, and large plants interfere with this practice.

The more woody flowering plants do quite well with me. A pink *Azalea*, bought a year ago, is again full of flowers, and a *Cytisus* is putting out buds. *Hydrangeas* are quite at home. The *Heliotrope* does not remain stocky, but it flowers very well.

I am troubled by few insects except the green aphid. They are always present in some quantity, and but for tobacco fumigating would do great harm. At the risk of the charge of uttering heresy, I confess I am inclined to the policy of including a few plants in a conservatory that the aphid particularly likes. A few *Cinerarias* this winter have taken to themselves nearly every aphid in the whole conservatory. But for them these pests would have spread to the *Callas*, *Oxalis*, *Farfugium*, *Hydrangeas*, and, indeed, nearly everything but the *Begonias*. The *Cinerarias* do not flourish, but their decline is not on account of insects.

Buffalo, N. Y.

John Chamberlin.

The Constitutional Health of Plants.—II.

To the Editor of GARDEN AND FOREST :

Sir,—In April, 1890, on about an acre of land, I set Strawberry-plants between rows of Grape-vines in a young vineyard. These rows made equal plats, five yards apart, one hundred yards long. Three rows of Strawberries, three feet wide, were set in each of these plats and grown in matted rows. During the summer of 1890 Strawberry-blight (*Sphærella Fragariæ*) became epidemic over this entire patch of Strawberries.

In April, 1891, I sowed nitrate of soda broadcast, 250 pounds per acre, on the southern halves of alternate plats of these Strawberries.

In June the contrast between the treated and untreated plats in color and luxuriance of growth of plant and in yield and excellence of fruit was remarkable. Where the nitrate was applied the plants stood fully three times as high as those not treated, and they were of so dark a green that they were plainly distinguishable in color from the untreated plats at a considerable distance. The yield of fruit doubled under the nitrate and lasted longer, giving two more pickings of good berries.

On the nitrated plats there was not any blight, while on those without nitrate the blight was prevalent, as it had been on the entire field the year before. Late in August the fungus did appear on the treated plats, but the attack was slight.

I may mention also as instructive that on the plats not nitrated in April, 1891, nitrate soda had been applied in November, 1890.

From this autumn application no effects were visible; there was no improvement in growth or in fruit, and no exemption from the fungus disease; no difference in any respect between the portions of these plats nitrated in autumn and the portions to which the nitrate had never been applied.

This experiment teaches that—at least as a fertilizer for the Strawberry—the effect of nitrate of soda is immediate, but transitory, and that it is useless to apply it in autumn to leach out of the ground before growth begins next year.

Whether nitrate of soda directly destroys the germs of the fungus causing the blight I cannot say. When in late August this blight came on the plants which had been treated in April I gave a portion of one of them a free sprinkling of nitrate of soda. It blasted the foliage and stems and severely injured the crowns of the roots of the plants. A very weakly growth again started from them, but it was evident that the medicine thus administered is too strong for the patients' constitution.

As a preventive of Strawberry-blight it is probable that the nitrate of soda is effective simply by stimulating vigorous growth of the plant, strengthening vitality to a degree which enables it to resist successfully the attack of the disease. Among organized beings everywhere we see examples of this mysterious resistance of individuals to epidemic influences. Not all persons take the small-pox or the cholera.

Life contends against life, and it seems that the vital strength of the higher organism resists the vital action of the lower, but since we do not yet understand what life is, we can hardly consider this guess as an explanation.

In the case of various plants I have seen remarkable evidence of the benefit from the use of nitrate of soda applied to the soil just at the commencement of growth, or during its progress. And this benefit was especially noted in the comparative exemption of such plants from the attacks of insects and fungi.

It is essential, however, that the soil treated with nitrogen should be supplied with all the other elements of plant-food. Unless these be present the stimulus of the nitrate will be of little help.

Increased vigor of growth, secured without fertilization, sometimes seems to give the power of resisting disease. I have four *Kirtland Pear-trees* planted together in the orchard, which for years have been subject to attacks of the fungus, causing leaf-blight and the cracking of the fruit (*Entomosporium Maculatum*). By the last of August the leaves were all blighted and shed, the fruit was all cracked to the core and totally worthless.

These trees are thirty years old and were twenty feet high. When I learned that spraying with the copper solutions is protective against this blight, I arranged to spray these trees. To make them more accessible, and to more conveniently harvest the crops of fruit expected under this treatment, I cut back the tops of these trees, taking two-thirds of the length of each branch. This severe pruning was done in April, just as growth began. The trees pushed a vigorous new growth, making a dense mass of fresh sprouts and foliage. One of the trees was left unpruned, and it furnished a chance for comparison. For some reason the spraying was neglected, and

in late summer, when the Pear-blight was epidemic, severely pruned trees were not attacked, while the tree left unpruned was ravaged as usual by the fungus.

The contrast between the apparently perfect health of the pruned trees and the disease of the unpruned tree was vivid. The unpruned tree dropped all its leaves and pears in August. The pruned trees matured what fruit they bore, and held their foliage green until frost.

The next spring (1891) I left all the trees without any protective treatment. The unpruned tree was again completely desolated by the fungus. The pruned trees were healthy, maturing fine fruit and leaves.

Experiments hitherto have been chiefly made to test the efficacy of applications which serve as external defense to the plant against invasions of its foes. There is reason for hoping that we may make this protection more efficient by some fertilization or medication to stimulate and strengthen the constitutional health of the plant. We use special nutrients and tonics against epidemic diseases of the human family; there may be found other nutrients and tonics to promote the health of plants. The most promising of these are lime, potash and the nitrates and sulphates of soda and potassa; also sulphate of iron. With the exception, perhaps, of the nitrate of soda, to get the full benefit of these chemicals in promotion of plant-health, the plant requires some time to appropriate them to its uses. In my horticulture the beneficial effects of strong applications of lime and ashes given to plants three years ago are now just becoming apparent.

Vineyard, N. J.

A. W. Pearson.

The Danger of Delay in Acquiring Land for Public Use.

To the Editor of GARDEN AND FOREST:

Sir,—Mr. Harrison's letters on "The Shore Towns of Massachusetts" have possessed a vivid personal interest for me apart from their value as warnings against the danger of delay in securing public ground. Most of the area of which he speaks is familiar to me, much of it hallowed by associations of childhood and early life. It is not pleasant to reflect that I might now be ordered off as a trespasser from scenes which call up memories of friends and relatives whose honorable services have contributed to swell the maritime glory of Massachusetts.

But I wish particularly to enforce the lesson of these letters by specific examples. More than thirty years ago, when the late Nathaniel Silsbee was Mayor of Salem, he conferred with me on the possibility of preserving nearly the whole of the picturesque point of land then known as "The Neck," which separates the harbor of Salem from that of Beverly, the eastern point of which is spoken of by Mr. Harrison as "The Willows." It was then a rocky tract of utterly waste ground, with hills commanding magnificent views of the ocean, and containing the ruins of old Revolutionary forts. The only building on the tract was the almshouse, and it all belonged to the city. By request of Mr. Silsbee, after several discussions, I prepared a design for the arrangement of the larger portion of this tract as a public park, in which the old forts were included, and most of the ocean-front kept open for pedestrians, with a drive-way which in its course revealed all the finest views, while a large area outside was reserved for subdivision into building-lots for summer residents, who would be attracted to the place whenever it was thus improved. Mr. Silsbee made every effort to have the plan adopted, and urged upon the City Council the fact that here was one of the most attractive sites on the eastern shore, nearer to Boston by many miles than those between Beverly and Gloucester, which were then just beginning to be taken up for private occupation, and that Salem would thus secure a possession of unrivaled interest, besides making very valuable property of a then almost worthless piece of land. That was more than thirty years ago, and had the plan been carried out the drives and walks would long before this have been shaded by well-grown trees, and Salem would have possessed an unrivaled ocean park, that would have added a unique feature to those which her maritime history and quaint characteristics have already secured for her. But nobody could be brought to consider this other than a visionary scheme, and no action was taken upon it. The plan was returned to me, and I preserved it in the faith that time would vindicate the truth of its value, but it perished in the great fire of Chicago in 1871.

Another instance from my own experience is that of the Middlesex Fells, which Boston is now trying to secure after much of its beauty has been destroyed. It must have been as early as 1856 or 1857 that I invited a number of gentlemen to visit the place with me, and we spent an afternoon riding and walking

through the magnificent woods, over the picturesque hills, and on the shores of the beautiful lake of three hundred acres, on which only one house had then been erected. It was all wild, and could then have been had, comparatively, for a song, and I pleaded with all the argument I could command that it should be secured for the future use of the city and kept in its wild condition till wanted. The gentlemen who accompanied me were impressed with the beauty of the place, and to some of them it was a revelation that such a tract existed so near the city; but George S. Hillard, who was one of the party, doubtless expressed the sentiment of all when he said: "You might as well try to persuade the Common Council to buy land in the moon."

Such reminiscences may seem idle, but surely, experience ought to teach wisdom, and actual examples tell with greater force than general statements. The instances cited are only illustrations of what is happening to-day in every growing city, and in my forty years' experience as a landscape-gardener I have witnessed such lamentable results of the "peuny wise, pound foolish" policy that I feel impelled to sound a warning whenever opportunity offers.

Minneapolis, Minn.

H. W. S. Cleveland.

Apples for the North-west.

To the Editor of GARDEN AND FOREST:

Sir,—Mr. E. P. Powell's list of Apples may answer for the part of New York where he lives, but it is generally presumptuous for an eastern man to make out a list for "the north-west" or any other territory with which he is not familiar.

Seek-no-further is the only one of his list we can recommend here, and only for very favorable locations at that. Even this is better top-worked on Virginia Crab stock or Hibernial stock four feet above ground. We do not know Kirkland and Belle Bonne; if they are hardy we should like to try them top-grafted on Hibernial. Jonathan, Salome and Grimes' Golden we are trying top-worked. In 1854 we set out twelve acres of orchard, making our selection from the books and such other recommendations that would do well enough for New York, Ohio and Michigan, but we never raised a bushel from our northern Spies, Greenings, Roxbury Russets, Swaars and Wagners all put together. Having some recollections of New York Apples, and remembering Janesville was about on the same parallel of latitude, we foolishly thought it safe to plant such varieties as did well in our old home. Those eastern varieties grow too late, and do not ripen wood for winter. We want such varieties as Duchess of Oldenburg. We are fairly successful, with care, on good timber soil with Red Astrachan, Sops of Wine, St. Lawrence, Lowell, Yellow Transparent, Wolf River, Alexander, Fameuse, Wealthy, McMahan, Hibernial, Switzer, Longfield, Tallman Sweet, Newell's Winter, Roman Stem, Golden Russet, North-western Greening, Windsor Chief, Avista, Alden, Willow Twig, and many new seedlings that are coming to the front. Seven of these mentioned are Wisconsin seedlings, and have become standard sorts. We are much pleased with Patten's Greening and Iowa Beauty, from Iowa, and Peerless, from Minnesota. We are on the hunt for those varieties that will rival eastern fruit in quality and productiveness.

It is fashionable to decry Ben Davis, but this is the most profitable Apple that can be grown in the latitude of St. Louis, and a southern Ben Davis is not a bad Apple; grown at the north it is of poor quality. After some bitter experience, we are learning in Wisconsin that our best orchard sites are on the northern slope of timber clay ridges, with no protection except from south-west winds; that we should plant only hardy varieties, and trees grown at the north; that a tree should be pruned to one central stock, with side branches about eight inches apart at the time of planting; that every fruit or shade tree should be protected by a screen which shades the body summer and winter. This will protect from sun-scald and the borer, and the best protection against these, as well as against rabbits and mice, is a lath and wire screen, made by weaving lath with small wire, and encircling the tree with it. This will last eight years, and is the best and cheapest device we have found.

Janesville, Wis.

George F. Kellogg.

Notes.

In Philadelphia the Ulrich Brunner has been in greater demand than any other Rose this winter.

The house and garden of the late Alphonse Karr, on the Riviera in the south of France, have been purchased by some of his friends, and are to be preserved as a memorial of the

famous author, whose later years were entirely devoted to the cultivation of flowers.

In a letter testifying to the hardness of *Citrus trifoliata* in Philadelphia, Mr. Joseph Meehan writes that even the ordinary Lemon-tree will often survive the winters there when left out. One tree lived unprotected through two successive winters, after which record of it was lost.

Jedediah Hotchkiss writes to *Science* that while the Confederate soldiers were encamped in the vicinity of the Rappahannock River in 1862-63, not only they, but the inhabitants of that region, used freely the leaves of the common American Holly (*Ilex opaca*) as a substitute for tea.

The *American Architect and Building News* recommends, as likely to be of practical assistance to persons interested in the subject, a pamphlet on "The Disposal of Sewage for Isolated Country Houses," written by Wm. Paul Gerhard, C. E., and recently published by the Iowa State Board of Health.

More than three thousand persons are employed by the famous firm of Moët & Chandon in the cultivation of their vineyards near Epernay, the centre of the champagne district of France. The cellars in which the wine which they produce is stored, cover an area of about one hundred thousand square yards, and are cut out of the solid chalk beneath a hill.

Including the Central Park and the new parks in the northern portion of the city, which as yet are hardly available as such, the vast area of New York contains twenty-three breathing-places, large and small. In Berlin, in addition to the Thier Garten, there are three other large parks and about thirty open places, variously planted, and, even when very small, usually containing statues or other works of art.

Many Japanese flower-vessels are formed in the shape of a boat. Such vessels, according to Japanese ideas, must always be suspended in an elevated position in order both that the idea of their floating may be expressed, and also that the water they contain may not be seen; for taste would be grievously violated if water were visible inside a flower-boat, suggesting a leaking or wrecked vessel, and therefore giving birth to ominous suggestions.

A Philadelphia correspondent of the *American Florist* speaks of a new bright pink Carnation which is now being propagated in that city by Mr. Colflesh, and another light pink variety of Robert Craig's named Edna Craig, which is pronounced exquisite in color, of good size, and with a heavy stem. These two, with Mr. Lonsdale's Grace Battles, another promising pink variety which has been mentioned before, are soon to be offered to the public.

Professor Halsted, who has charge of the Exhibition of Weeds at the Chicago Columbian Fair, has sent out a circular requesting specimens from all states and territories. Seeds are especially desired as well as seedlings in various stages of development. The root-system, flower and flower-cluster and seed-vessel are also essential. If the weed is large, specimens must be procured while they are small enough to mount the whole plant, roots and all, upon a herbarium-sheet not over a foot in length. The collecting must be done during the present season, and the specimens sent in for mounting, labeling, etc., by the 1st of December.

Mr. W. R. Lazenby reports in the *Bulletin of the Torrey Botanical Club* that he has compared the catalogue of the plants of Franklin County, Ohio, published in 1891 by Messrs. Selby & Craig, with the list, covering the same district, which Professor W. S. Sullivant issued nearly fifty years ago, and which was considered a conscientious one at that time. The total number of plants now credited to the county is 1,002, as against 779 in the early catalogue. Of this total number fifteen per cent. are introduced plants; but when the additions to the old list, numbering 223, are considered by themselves the proportion of foreign plants amounts to nearly forty per cent.

A book likely to be of great value to tourists has recently been published in Paris under the title *Autour de Paris*. Its author is Monsieur Louis Barron, and it gives, in charming language and with much historical information, descriptions of all the interesting towns, buildings, landscapes and gardens in the vicinity of the capital, supplying a much-needed guide not only to such famous spots at St. Germain, Fontainebleau, Chantilly and Versailles, but to a multitude of others which, while almost equally delightful, are less celebrated, and therefore have usually been unvisited even by the most eager and industrious of foreign travelers. The work is published by Quantin.

Foreign papers describe an amusing exhibition which was recently held in the park at Brussels. The Burgomaster appointed a certain day when the sculptors of the city might display their skill in the rapid modeling of figures in snow, and the public would be admitted to view the results of their skill for a small admittance-fee, the money going to charitable objects. A number of sculptors entered the novel arena; by sunset their work was finished, and during the evening it was examined under the electric light by crowds of people. The most conspicuous work was a colossal figure representing Charity, while others were of a more "realistic" sort, notable among these being certain figures of nurse-maids and soldiers seated, after the manner of their prototypes, on the park benches.

The recently issued annual report of the Park Commissioners of Lynn, Massachusetts, is illustrated with charming pictures of the ground under their control, and it tells us that, although the town is a great manufacturing centre, the people who frequent the Lynn Woods "seem to have a sense of ownership which begets a feeling of care and responsibility for the property, which is a better protection than a police, however watchful, could give." Only three arrests were made during the year, and only one of them was for destruction of property, although the rules against breaking branches and picking flowers are necessarily strict; and no complaints of rowdiness or improper conduct were preferred. Prairie-hens and quail, introduced into the woods from the west, have made themselves at home and are breeding in a satisfactory way.

The Cauliflowers for which Erfurt is famous are grown on a low-lying strip of land some miles in length and intersected by warm springs which never freeze, even in this vigorous climate. The ground is cut into beds a hundred yards long by twenty wide, and the water flows around each in ditches about nine feet wide. The beds themselves are raised two or three feet above the level of the ditches, and the plants are watered with a bowl about the size of an ordinary hand-cup fitted to the end of a pole ten feet long, with which the water is taken from the ditches by hand and poured on and around the plants. This involves considerable labor during the hot summer months, but the plants flourish under such treatment and bring a very remunerative crop. Water Cress is grown in the ditches successfully, because the water is kept at an even temperature all the year round. Erfurt is one of the few places in Germany where Water Cress can be grown in quantity.

In Dr. Peter Heylyn's *Help to English History*, published at London in the year 1680, occurs incidentally an interesting bit of horticultural information. Describing the city of Gloucester, he says that the region where it lies is "a fruitful and a pleasant Country, being honoured with a full course of the River of Severn and the original fountain of the River of Thames. That part thereof which is beyond the Severn is overspread with Woods; all which included in one name, made the Forst of Dean. That part that butteth upon Oxfordshire is swelled up with hills, called the Cotswold hills; but these even covered, as it were, with Sheep, which yields a Wooll of notable fineness, hardly inferior to the best of England. Between these two is seated a most fruitful Vale, fruitful to admiration of all kinds of grain and heretofore of Vines and Vineyards; the want of which is now supplied by a drink made of Apples, called Sider, which here they make in great abundance." It certainly seems strange to-day to think of this western part of England as a region where cider was a comparative novelty, and where the manufacture of wine had been carried on.

Catalogues Received.

AMES PLOW Co., Boston, Mass.; Plows and other Farming Implements and Machinery.—WM. ELLIOTT & SONS, 54 and 56 Dey Street, New York; Vegetable and Flower Seeds and Bulbs.—WM. M. JOHNSTON, Wilmot, Stark Co., Ohio; The Daisy Force Pump and Sprayer.—C. H. JOOSTEN, 3 Coenties Slip, New York; Wholesale Trade Catalogue of Bulbs and Plants.—LÉNAULT-HUET, Ussy (Calvados), France; C. H. JOOSTEN, New York, Agent; Wholesale Catalogue of Nursery Stock.—RICHARD MOTT, Burlington, Vt.; Vegetable, Grass and Flower Seeds, Flowering and Foliage Plants, Trees, etc.—C. S. PRATT, Reading, Mass.; Price-list of Choice Strawberry Plants and other Small Fruits.—THE GEO. L. SQUIER MFG. Co., 189-195 Water Street, New York; Seeds, Roots, Plants, and Garden Requisites.—WM. STAHL, Quincy, Ill.; Fruit Trees, Plants and Vines; Excelsior Spraying Outfits.—PHIL. STRUBLER, Napierville, Ill.; Price-list of Small Fruit Plants.

Some Uses of Flowers.

AN article on this subject by the learned agriculturist, Pierre Joigneaux, originally published in the *Journal de la Ferme*, founded by him, and since his death reproduced in the *Revue Horticole*, has suggested some thoughts about the uses of flowers and the part which they play in our lives. Monsieur Joigneaux claims that the love of them is one of the important differences between man and the brute, but, unfortunately, modern science reveals that, after all, the primary cause of the color and fragrance in flowers was to make them attractive to birds and insects; and as the Poppy-bee and Australian bower-bird manifest quite as keen an appreciation as we do of their decorative value, the Frenchman's theory has no more substantial basis than the vainglorious assumption that the universe was made for man, and that he is superior at all points to other created things. But admitting all this, no sufficient reason why we should disparage or undervalue any pleasure is to be found in the fact that our lowly relatives, in their humbler way, can enjoy it, too.

It is an open question if the delight of the eye can ever be reckoned among the intellectual sensations, but whether the power to appreciate beauty is classed among our higher or lower faculties, the truth remains that flowers are relished and employed by man for ornament, even in his savage state, and this taste is not outgrown, but rather strengthened, as he advances in refinement, until in the great cycle of development the most highly organized civilization again touches the barbarian plane, in its love for sensuous enjoyment. The gratification of the human eye and nose being presumably more elevated than the joy of the donkey in his Thistle, or the humming-bird in its Bignonia, we are apt to plume ourselves upon this taste for flowers as an evidence of inward refinement, which it may or may not be, according to circumstances. A Nero may delight in his crown of Roses, while a Tarquin prefers to whip off the heads of his Poppies in a bloody dream of

tyranny, without leaving much to choose between them in ethical quality. But, however this may be, the love of flowers has a charming sentiment about it which gives it a high rank among the material sources of satisfaction; and the tendency of their presence to brighten and cheer lives otherwise devoid of color and fragrance touches our sympathies and gives food for the imagination. Thus the row of flower-pots in a cottage-window appeals to us more than the stately conservatories of a rich man's dwelling; the child's garland of daisies more than the belle's bouquet; the lilies on a coffin more than the roses that surround the bride; yet all are appropriate and precious, and cannot well be spared.

But, apart from what might be considered mere sentiment, flowers have played a considerable part in the history of civilization. They have given standards both of color and form that have had from the beginning a profound influence upon the plastic arts. They were probably the earliest suggestion of color to man, and from their roots, as a natural source, were distilled the earliest dyes. The Egyptian column is a reproduction of the stem and blossom of the Lotus-flower, at first realistic in shape and hue, and later conventionalized into that noble and beautiful form which still exists in the capitals of their majestic temples. The volutes of the Greek Ionic order, the Acanthus-leaf of the Corinthian, were suggested by common weeds. Gothic art borrowed from the garden myriads of lovely forms that were carved in stone into undying wreaths of beauty. Even the Hebrew, so reticent in natural form, was permitted to use the Pomegranate as a design upon the garment of the high-priest. The goldsmith has fashioned flowers in gold and silver, the lapidary has turned jewels into their likeness, the smith has reproduced them in miracles of wrought iron, the sculptor has modeled them upon his pedestals and adorned his statues with their semblance, the painter has borrowed from them his choicest decorations. To the poet they have been an unfailing spring of suggestion, whether as symbols or as a theme for dainty verse; the wisest and the gayest of the bards having alike immortalized them in powerful rhyme. Wherever art exists, whether of form or thought, flowers have been a potent spell to conjure with.

Thus from the earliest ages the life of man has been enwreathed with their fair forms, crowning him at banquets, smiling at him from his walls, twining around the columns and altars of his temples. They have expressed his love, his joy, his worship, his regret, his poignant anguish, in reality and symbol. The Greek hung a wreath upon his mistress's door; he wreathed the wine-cup with Roses, the victor with Laurel, the poet with the Bay, the guest with garlands; he crowned sleep with Asphodel, and death with Amaranth. This universal use of flowers almost seems to justify the belief that a love for them is one of the original passions of the human soul. No one who gives a handful of wild blossoms to a street child, whose life has been passed on a desert of stone, can fail to note how eagerly they are taken, and how tenderly, almost reverently, they are treated. Do the flowers satisfy a genuine hunger of the heart, or is this one manifestation of that larger affection, that feeling of kinship with all living things, which, in its various developments, we call the love of Nature?

Perhaps, however, the kindest office of flowers to man has been to inspire him with a love of gardening, a humanizing pursuit wherein their pleasant companionship affords unwearied delight. Here is a homely pleasure for all classes of people, from the road-side cottager, with his handful of Pinks and Roses, to the grower of all rare and splendid exotics. Here is a pursuit which beguiles the young into study and the old into congenial labor; which offers profound problems to the wise and simple pleasures to the unlearned; a resource which never fails; a delight which never stagnates into monotony, but leads on to new and ever-expanding fields as the seasons change and the years grow.

IT is to be regretted that a small fund cannot be raised to purchase Poe's cottage at Fordham and remove it, for perpetual preservation, to one of the new parks near by. "Until last autumn," says a recent writer in the *Epoch*, "the cottage had been kept in comparatively good repair by a widow, a woman of culture, who took great pride in the place and lived in the house. But the lady moved away on account of ill health, and a 'To Let' sign is now tacked on the cottage. The wealthy residents of this neighborhood look upon the little pastoral home as an eyesore, and are tired of answering the many questions constantly asked regarding it. The cottage looks forsaken; the doors are barred; across the windows are nailed boards, and everything about the place is going into decay. As it was opened for me a few days ago, there was a musty and damp smell about every room. The thin floor is giving way, and the ground beneath exhales a malarial dampness through the room where Poe wrote, and even the humblest people will not live in the house, owing to its unhealthy condition. I was told that the place was still visited by nearly a thousand people each year during the spring, summer and autumn months, and everything is pointed out: the room where Poe wrote his 'Annabel Lee,' and where, on January 30th, 1847, death released his child-wife, Virginia Clemm, from her period of suffering. But the historic pastoral cottage has seen its day, and, with the march of progress, it will soon be demolished, and its existence serve only as a memory, and to be told of by the 'oldest inhabitant' in the years to come." This is a very new country, and it will grow into a riper and more mellow age if some of the links which connect it with its earlier history are preserved. We therefore commend this interesting cottage in its distress to the literary men of New York, in the hope that some existing club or some special association of public-spirited men may be induced to rescue it from threatened destruction.

The Story of a Suburban Place.—I.

IN one of the large suburban communities just out of Boston, something like ten years ago, there was a wild-looking piece of land that rose abruptly from the street. A fringe of houses stood along the highway, but back of these there rose a wilderness of ledges and woods. An unkempt lane branched from the street here and curved up the slope. At the point where this stony byway disappeared from view, looking up from the thoroughfare, a picturesque house snuggled up against a Pine and Savin-covered ledge.

Few persons then appreciated the real value of land like this, and population for the most part had kept to the level ground. The lot was long and somewhat narrow, running from the lane beyond the point where it curved around nearly to a parallel with the highway below, and running down-hill to within a hundred feet or so of the street. It had an area of something over 30,000 feet, and was bought at a moderate price.

The land, mainly a rugged ledge, sloped abruptly both to the eastward and southward. A former owner had cleared most of the wild growth away, with the exception of that about the ledge, and had planted an orchard on the southern slope, where the neglected trees were making a slow growth. The land on either side had, for the greater part, also been cleared, but was mostly covered with a young second growth. The country, to the northward, was an almost unbroken wilderness of wooded hills, from which most of the timber had been cut twenty years before. This wilderness, near the lot, had been laid out in streets, which rambled in pleasant curves among the hills, and a little grading and blasting had been done, but the grades, for the most part, were fearful in their steepness.

Suburban street-railways were then unknown, and the nearest steam railway was almost a mile away from the greater part of the region, and the property had lain idle; but over the railway that accommodates this suburb there are now probably more trains in one hour than then passed over the line in the course of the entire day.

A third of the lot near the lane was sold to a friend for the sake of having a good neighbor, with the drive-way reserved to give access to the remainder. The site for the house was easily chosen. The considerations were, beside accessibility, the best possible view, together with plenty of sunshine and shelter from the cold winds. The southerly slope, close to the

ledge, seemed an ideal situation. The hill, rising behind, cut off the sweep of the northerly and north-westerly winds, while the prevailing winds of summer were from the southward and south-westward. The view was superb, commanding an uninterrupted range over something like two-thirds of the horizon.

The architect entered happily into the spirit of the scene, and made the best of his opportunities. The house composed admirably with the location. It was a two-story cottage of eight rooms, with basement of stone, furnished by blasting out the ledge for the cellar, the greater portion of three sides of which were above ground, on account of the slope. The wide-angled gables and broad eaves gave the house something of the Swiss character that harmonized with the rugged location. It was decidedly picturesque, with the merit of no uneasy striving for picturesque effect. Not a little amusement was afforded by the comments of towns-people who watched with interest the building operations. "No two windows alike, and not one of them over another. It's a sight to behold," said one. "How are you ever going to get there?" "How do you expect to get water on top of that hill?" were other queries.

The approach, however, was gradual enough, around by the lane and the drive-way, though looking directly up from the highway the house did tower up startlingly. The grocer's men and the like, together with casual visitors, always came toiling straight up across lots, and were pretty well winded on reaching the door. But, in spite of the commanding view and the impression of towering height conveyed by the almost precipitous relation of the site to the street below, the elevation was only about sixty feet above sea-level, and something like fifteen feet less than that above the main street. As to the water question, since the source of the town-supply was about twice as high as the ridge-pole of the house, no difficulty was experienced.

The house proved as pleasant and convenient as it was unconventional. The windows were made broad, so as to admit as much light and sunshine as possible. More wall-space was gained in the rooms, and concentration of light, together with the effect of bay-windows without the expense, by bringing the windows in the living-room and dining-room close together at the corners. The hall was made large, with a fire-place opposite the door, and an entrance to the sitting-room by double sliding doors that were seldom closed it was practically a portion of the living-room, which thus was about doubled in size. A projection of one story, which gave a pleasant variety to the exterior, was devoted to a small library and study, but there proved to be some objections to a study off the hall, even in that quiet neighborhood, and the establishment of a den in a portion of the yet unfinished attic space is contemplated.

The windows were left without blinds, which are rattling nuisances. In that breezy place the sunlight seldom becomes oppressive, and in the summer sufficient shade is given by awnings, which aid in agreeably clothing the house. The common American awning, however, is a hot-air trap, holding the heat in its hood like a hot-air balloon. Therefore the example of Mexico and other southern countries was followed by making the awnings a foot or so wider on each side than the windows and not closing in the sides, which gave ample shade and allowed the hot air to escape freely.

It seems a pity, however, that the most of us are debarred from making application of the experience gained in building a house by building over again and carrying out the ideas thus gained. One thing learned is that all windows should be casements, after the sensible continental European fashion, so that the benefit of the full air-space of the window-opening may be had whenever desired. We Anglo-Saxons have carried our sliding window-sashes into all parts of the world that our race has colonized; even the most unsuitable climates, like Bermuda, the British West Indies and California. In those warm climates, where all the air circulation is needed that can be obtained, half the window-space at least must thus be closed by glass. The same holds true of our northern American summers, which, with their humidity, often give us the additional annoyance of causing the sash so to swell in its frame that the utmost exertion cannot stir it, thus depriving us of fresh air altogether. It is possible now to construct casement-windows so as to be as tight as needed. The ideal window is a double casement, with the outer one so constructed that the frame will hold glass in the winter, to be removed in summer and replaced by wire netting to keep out the flies and mosquitoes.

The lower story of the house was clapboarded, and the upper portions were shingled, and the whole painted. The colors are harmonious, and the paint has stood phenomenally well, looking practically as fresh to-day as when applied nine years ago. But if the house were to be built again it would be plas-

tered externally. In this way a more substantial effect is gained, and the considerable expense of periodical repainting may be avoided. It would also greatly increase the warmth of a house in winter. Plaster has been proven to stand our climate admirably, and it seems the best possible material for country-house exteriors. A variety of effects may be gained by using either rough-cast or smooth plaster-work, or by mixing any desired coloring matter, like brick-dust, for instance, in the plaster. The surface may also be colored by wash or paint. Painted wood when weather-beaten looks shabby; painted plaster becomes picturesque with its delicate tones, like the effects in Spanish-American cities. Another advantage is the freedom with which climbers cling to the surface, while they have usually an unconquerable repugnance for painted wood. Next to plaster comes a shingled and unpainted exterior, which, assuming very quickly a soft stone-gray, makes a house look as substantial as stone, and gives it a rightful place in a rural landscape. Climbers will cling readily to the shingles. Pleasant effects are also gained by the use of stains on the shingles, which may be easily renewed, or, better still, may be left to blend under the weather. But a shingled exterior should never be tidied up with paint. Clapboards are almost hopelessly prosaic in effect.

The piazza on the easterly side of the house makes substantially an outdoor room for summer afternoons and evenings. It is of generous width, and covered at the entrance. Adjoining the living-room, which communicates with it by casements, it is roofless, but an awning affords all necessary shade. A piazza should never be permanently covered on the sunny sides of a house where there are windows.

Here on the piazza there are blossoming house-plants, together with a large Oleander in a tub. A rug is spread beneath the awning; there are tables and chairs, and supper is sometimes served here. The view is a source of unwearying delight. So abruptly does the southward slope fall off that the immediate foreground is not visible except from the edge of the balustrade, making the effect of the piazza much like that of the hurricane-deck of a steamboat. The range is from Nahant to the eastward, around to the Menotomy Hills, in Arlington, to the westward. The central point is the State House, with its glittering gilded dome, five miles away as the crow flies. The great city spreads on all sides, its political limits indistinguishable as it merges in the mass of the Greater Boston that extends to our feet. Our hill-side forms part of the ancient rocky coast of the Boston basin, and a rise of but a few feet would again bring the salt-waters of the bay up to its former shores. It is hardly more than a stone's-throw down into the level of the wide alluvial plain over which the tides once rolled. This plain spreads away to the blue gleam of the Mystic. When the house was built it was an almost unbroken pastoral expanse, dappled here and there with trees, and broken with woodland areas, the successors of the noble Oaks that went long ago to form the timbers of the East Indianmen launched from the Medford ship-yards. Last year all but a patch of the woodland vanished before the axe, for it was there that the Gypsy Moth began its ravages, and the remedy was to destroy the trees.

Very soon after the occupation of the hill-side the plain began to be checker-boarded with streets, and houses began to dot themselves over it. The effect of these packing-box structures was most discordant at first. But as they multiplied, their isolated ugliness vanished as they became merged in the mass that soon covered the ground and joined itself to the sea of buildings that spreads in broad undulations over the hills and valleys of our rapidly growing suburban city, blending indistinguishably with the neighboring municipalities that ultimately must become one. The commonplaceness of urban edifices gives way to a striking impressiveness when beheld in a mass, with a confusion of roofs and gables intermingled with the verdure of tree-tops that nearly bury them for half the year, visibly symbolizing the efforts of Nature to overwhelm the works of man and reconquer the ground he has made his own.

There is one broad space where the sea of houses holds back—a wide expanse of salt-marsh like a grassy lake. At times the silvery threads of its embroidering creek swell and spread until the marsh becomes for a brief time a veritable lake—a beautiful vision as ephemeral as the sunset's glow.

The view includes some notable historic details. Less than a mile away by the Mystic's side may be seen the roof and chimneys of a brick dwelling, the oldest house in New England, and in the United States outside of the once Spanish domains of Florida and New Mexico, the mansion built for Governor Cradock, but never occupied by him. Near by was launched in 1632 the Blessing of the Bay, the first vessel

built in New England. Beyond the Mystic rises the picturesque old pre-revolutionary powder-tower in Somerville.

In Charlestown the great shaft of Bunker Hill monument is rivaled by the more slender chimney of the Navy Yard machine-shop. About the huge bulks of the grain-elevators in Charlestown and East Boston are congregated the masts of the shipping in the harbor; the harbor itself cannot be seen from here, but the long blue line of the Atlantic shows over Nahant from the ledge above. At night the red glimmer of Egg Rock light may be seen from the piazza, and from the upper windows are visible the steady glow of the lighthouse on Long Island head, and the intermittent flash of Boston light at the harbor mouth.

The contrast between the life and stir of the metropolitan landscape in front, where the city is backed by the majestic wave-lines of the Blue Hills, is great. The smoke rises from countless factory-chimneys; the fleecy steam-drifts mark the flying shuttles of five lines of railway; the incessant hum of traffic comes faintly to the ear; then the almost absolute seclusion roundabout, with the sylvan wilderness rolling away behind. By our neighbor's house, just below and across the way, the pioneer of our friendly group of three, there nestles a pretty lakelet among the fells, its calm surface glimpsed from the piazza above the tops of the Apple-trees that happily cut off the sight of a row of prosaic dwellings. This lakelet, which occupies a former swamp and forms a reservoir for the great factory of our suburb, occupies the hither end of a valley along which there is a vista to some hills—far enough away for a soft haze to intervene—that stand in a park now private, though likely some day to become a public domain.

The changes of the day and night lend constant charm to the landscape from this piazza—its aspects under sunshine and cloud, under summer verdure and winter snows, the flushing tints of spring-time leafage that seem prophetic of the vivid tones of autumnal glory; the sweet languor of summer nights with a mystery of darkness below and above, the city lights far and near repeating the firmament's constellations almost as though mirrored in a lake, and the enchantment of the moonlight scenes, under which the plain sometimes becomes transformed into a white sea of mist, with the dim and vaguely outlined bulks of trees and buildings rising darkly from the surface like the islets of an archipelago.

Boston.

Sylvester Baxter.

Notes of a Summer Journey in Europe.—X.

FROM Berlin an excursion was made to Copenhagen with the object of comparing the dendrological collections of this northern station with our own, so that, if found worth while, arrangements for exchanges might be made. Although Copenhagen is situated in a latitude which corresponds to that of north-eastern Labrador, it enjoys a somewhat insular situation and reaps much benefit from the modifying influence of the great Gulf Stream. From the character of the vegetation I was prepared to find indications of a winter climate somewhat similar to, or a little colder than the winters in eastern Massachusetts. It was quite a surprise, therefore, to find here trees of the English Walnut, good specimens of *Sequoia gigantea*, to be told that *Vitis vinifera* matured fruit in some favorable situations, and to see thick borders of *Fuchsia Riccartoni* and *F. gracilis*, two or three feet high and in full bloom, which remain out all winter with only a moderate covering of leaves and rubbish. Even the Fig can be grown against walls if afforded winter protection. When the mercury falls to about zero of Fahrenheit at Copenhagen the weather is considered extremely cold. Therefore it is possible to grow here many trees and shrubs which will not survive the winters of eastern Massachusetts.

There are practically two botanic gardens in Copenhagen, each being under the control of separate institutions. These are the University Botanic Garden and the gardens of the Royal Agricultural and Horticultural Academy. The first presents no novel features and few remarkable plants, or plants which are not to be found in the other. It was of interest to note here both the typical and the yellow or amber-colored fruited Choke Cherry (*Prunus Virginiana*), sixteen or eighteen feet in height and with thick single stems. In many parts of America the Choke Cherry is counted as a mere shrub, but in some places it really becomes a neat single-stemmed tree, so that, from its habit, it might almost be counted a distinct species from the shrubby race. The yellow-fruited form is apparently quite uncommon, and to it has been given the varietal name of *erythrocarpa*. In this garden there are fine shrubs of *Jamesia Americana*, while handsome masses of the so-called Oregon Grape (*Berberis Aquifolium*) were bearing an abundance of fruit. *Lonicera alpigena*, about seven feet in height, was very showy, with large rich red fruit. The plant which inter-

ested me most was a flowering specimen of what I at first took to be a white-blossomed *Potentilla fruticosa*. It was without name, and no information could be obtained concerning it. In making inquiries afterward at various botanical establishments and of persons eminent for their knowledge of such things, no one seemed to know anything about it. The plant was seen again in the Edinburgh Botanic Garden. There seems to be no doubt that this is the *P. glabra* of Loddiges, or what has also been called *P. Dahurica*, small colored figures of which are to be found in *Loddige's Botanical Cabinet*, t. 914, and in *Gartenflora*, vol. ix., t. 278. It is said to have been introduced from Siberia, and is, therefore, a plant which should be perfectly hardy in all northern gardens. It was early introduced into cultivation (in England as early as 1822, according to Loudon), and it is hard to tell why it should have been allowed to become almost lost again. It grows to about the same size as *P. fruticosa*, from which it chiefly differs in its white flowers, and in being smooth in all its parts instead of pubescent or hairy.

The gardens of the Royal Agricultural Academy were established about thirty-two years ago, and are now mainly under the general charge of Dr. C. Hansen. Necessarily they include much more than the other, and, besides the natural species of ligneous plants, portions are devoted to experimenting with and growing of fruits, vegetables, cereals, etc., work necessary to an institution of this kind. Here, also, new varieties are tried, practical tests of the value of manures made, and other experiments carried on which may prove useful to the students.

This garden is interesting and instructive in various ways, and the grounds and specimens present a very creditable appearance, especially considering the very moderate sums allowed for their maintenance. For popular instruction there are separate beds made for plants of economical interest, so that the different species may be seen together, which are valuable for any particular quality. In this way instructive object-lessons are given in textile, food producing, sugar producing, gum and oil producing, aromatic, tinctorial, medicinal, poisonous, and other classes of plants likely to interest not only trained students of science, but every one at all interested in these subjects. All the species are very distinctly and neatly labeled, each with its botanical and common name, its original habitat and the peculiar property or quality for which it is noted. A feature, not often carried out to such an extent in other economic collections of this kind, is the exhibition of the seeds and sometimes of the products with the living plants. The seeds are first thoroughly dried, then carefully sealed in specially made jars, which are then placed in an inverted position on a suitable stand or support beside the living specimens. Characteristic fruits or products are also sometimes shown in liquid. Such a collection of bottles and jars with the plants does not give a pleasant aspect from the artistic point of view, but genuine educational advantages are thus afforded. Considering their limited area and how much ground is necessarily set apart for strictly practical or educational work, the grounds of the Academy contain a fair collection of trees and other hardy ligneous plants. *Holodiscus* (*Spiræa*) *discolor*, *ariæfolia*, has become a handsome bush, fifteen feet across and twelve feet high, and the mild moist climate has induced many other shrubs to grow in corresponding proportion. The plant given the name of our Smooth Sumach (*Rhus glabra*) was not that species, but seemed more like the Stag-horn Sumach (*R. typhina*), and may possibly be a hybrid between the two. This is mentioned here because the true typical *R. glabra* was not seen in any European garden visited by me, although in some gardens the cut-leaved variety (var. *laciniata*) is cultivated. *R. typhina* is common. The intermediate form, usually called *R. glabra*, also goes by the name of *R. viridiflora*.

Another very different species of *Rhus* is passing as *Ampelopsis Japonica*, but its trifoliate leaves, rooting stems and milky juice at once indicate that it is a *Rhus* very closely allied to, if not identical with, our Poison Ivy (*R. Toxicodendron*). This so-named *Ampelopsis Japonica* has been distributed as a novelty by a well-known English firm, and in Germany I found it planted as something choice to form a covering for the supports and sides of a much-used arbor.

The tips of the branches of the Plane-trees here seemed affected by some disease which caused injuries similar to that caused by the fungus in America.

The director of the garden has made some attempt at a geographical arrangement of his plants, and in the little space devoted to the flora of Greenland there are several woody plants which have been brought from that cold region. Perhaps the most interesting of these is a fruit-bearing specimen of an American Mountain Ash.

In labeling the trees white porcelain labels on iron stakes are much used, but plain zinc labels are also largely employed, while others of a more elaborate kind are furnished with a little map showing the geographical distribution of the species.

In this garden and vicinity there are fine hedges of English Hawthorn, Box, Privet, Hornbeam (*Carpinus Betulus*), and a beautiful close compact one, ten feet high, of the European Field Maple (*Acer compestre*).

One of Dr. Hansen's hobbies is conifers, and at the Arboretum, or Forest Botanic Garden, at Charlottenlund, several miles out of Copenhagen, he has been enabled to accumulate a larger collection of these than is possible in the city garden. This experimental arboretum only covers eighteen or twenty acres of ground. It is said to have been established over fifty years ago, and it is now practically a branch station of the Agricultural Academy. Although much crowded, some of the trees have attained a good size. Among other evergreens there are large and fairly well-developed examples of *Sequoia gigantea*, *Abies grandis*, *Picea Sitchensis* and *Pseudotsuga taxifolia*. The last is counted the fastest-growing. A tall specimen of *Alnus glutinosa*, with a trunk two and a half feet in diameter and the aspect of a sturdy Oak, is one of the finest trees on the place. Laburnums do well here, while such American plants as *Ilex verticillata*, *Amelanchier Canadensis* and *Viburnum prunifolium* are quite as well grown as any to be seen in cultivation. Of the conifers, the director's specialty, it is claimed that there are about six hundred species and varieties here. The plants are mostly still very small, and, of course, there is not room for any sort of development in size. Such an extraordinary number of so-called varieties is accounted for by the fact that extremely slight variations are recognized and propagated. Of Lawson's Cypress, for instance, there is said to be at least fifty-two different kinds. Most of these forms are of no particular value or interest except to a student or enthusiast. It is claimed that they vary in point of hardiness, but a greater difference would undoubtedly be found by selection from natural habitat.

The scope of these notes will not allow of a more extended notice of the Copenhagen gardens. While not differing enough from other gardens to make a long journey worth the while, they deserve a visit by any one interested in botany or horticulture who may happen to stray into this region.

The Beeches of Denmark are far-famed, and many fine Beech and Oak forests are frequently seen. It is said that there are only two species of conifers now indigenous to the country. These are the common Juniper (*Juniperus communis*) and the Yew (*Taxus baccata*), the latter being very rare and local. That the climate and soil of some parts of Denmark are suitable to the growth of trees and arborescent vegetation is shown in a fine forest at Klampenborg, a few miles north of Copenhagen. Here the common European Silver Fir (*Abies pectinata*) is to be seen with beautiful stems a hundred and twenty feet in height and three or four feet in diameter as high as one can reach from the base. These trees were originally planted alternately with rows of Beech and Oak.

Practical forestry receives some attention in Denmark. Large areas of the waste lands are annually planted with the little Mountain Pine (*Pinus montana*), so that eventually these now worthless tracts may prove of value, and, in the process of nature, obtain some degree of fertility.

Arnold Arboretum.

J. G. Jack.

Plant Notes.

Erica hyemalis.

FIFTY years ago there were between three and four hundred species and varieties of Cape Heaths in cultivation in England. They were popular with amateurs, collections of them being as frequent almost as collections of Orchids are now. Few of these Heaths remain in our gardens. As a rule, they are disliked because they require too much attention for the ordinary collection, while for specialists the genus has apparently lost its charm. There are, however, at least two *Ericas* which have kept a leading place among popular garden-plants—namely, *E. hyemalis* and *E. gracilis*. With regard to the former, it may be said with truth that no other plant is grown in such enormous quantities for the London market. At least a dozen nurserymen might be named whose annual output of this one Heath amounts to from twenty to thirty thousand plants each. Such a specimen as that represented in the illustration on page 137

may be bought in Covent Garden market about Christmas-time for eighteen pence. The plants are usually in five-inch pots, and the shoots average a foot in height. The flowers

perish almost as soon as the flowers—that is, all those which find their way into the window of a house or into a small greenhouse. And this accounts for the enormous

Fig. 21.—*Erica hyemalis*.—See page 136.

remain fresh for at least a month. The popularity of this Heath is thus easily accounted for: it is cheap, very pretty when in flower, and lasts just long enough to satisfy the masses who like window-plants and change. The plants

number disposed of every year. In England *E. hyemalis* is certainly one of the most valuable market-plants ever introduced.

It is strange that a plant which has enjoyed an excep-

tional popularity in England for something like fifty years should never have been figured in any English publication or work until now. I have not been able to trace the origin of the plant, nor find any picture of it in any book to which I have access here. Nor can any of those who have paid attention to garden Heaths assist me. The venerable Mr. John Fraser, of the Lea Bridge Nursery, once famous for its Heaths and New Holland plants, informs me that he purchased three plants of it from the Pine Apple Nursery about forty years ago. Cultural directions for this and *E. gracilis*, I find, were given in the gardening papers of thirty years ago. Probably the plant is a seedling or hybrid; at any rate, it is not represented among the wild specimens in the Kew Herbarium. It is not mentioned by Andrews in his beautifully illustrated work, *Colored Engravings of Heaths*, published in 1809. Singularly enough, Andrews states, under *E. Linnæa superba*: "This fine plant has ornamented various collections for the last five or six years. In growth it is luxuriant, as we have frequently seen it two feet high with numerous long-flowering branches at Covent Garden among many of the most beautiful (if not most rare) *Ericas*, which are exclusively cultivated for that well-known emporium. It may certainly be considered as one of the finest variations of *E. Linnæa*, and as such its hyperbolic specific title may serve to distinguish it from most varieties." Were it not that the plant thus described is stated to flower in "May, June and July" I should have accepted this as being identical with our *E. hyemalis*. In Loddiges' *Botanical Cabinet* (t. 102) there is a figure of *E. Linneana*, which is there stated to "flower rather early in spring and is of pretty long duration. We consider it a very ornamental sort. The buds are in general formed before the winter, and if it is kept in a bad greenhouse, where the smoke escapes from the flues, the buds are very apt to blight. We have known them preserved exceedingly well in a frame, carefully attended to in winter." In my opinion, *E. hyemalis* is somewhere very near these two. In De Candolle's *Prodromus* both *E. Linneana* and *E. Linnæa superba* are referred to *E. perspicua*. This species, as now known, flowers from April to November. It was introduced from the Cape to Kew about one hundred years ago. Several varieties of it are known, and, if the *Prodromus* is correct, we may conclude that *E. hyemalis* is probably a winter-flowering variety of *E. perspicua*. It is difficult to believe that the raiser of such a plant would not have claimed some credit for it. So much for what we know of the origin of this beautiful Heath.

In its cultural requirements *E. hyemalis* is simple enough, but the grower must stick to those requirements or he will certainly fail. In the nurseries of Messrs. H. Low & Co., where about thirty thousand plants such as that figured are annually grown, the method of culture for this Heath is as follows:

PROPAGATION.—Cuttings are selected in September or October from the branchlets which crowd the base of the plants. They are cut to an inch in length, and the lower half is carefully stripped of leaves. The cuttings are then pricked in well-drained seven-inch pots of very sandy peat-soil and covered with bell-glasses. The pots are placed in a north house, where the temperature is kept at from fifty-five to sixty degrees. The bell-glasses are removed and wiped inside every morning, and any pots which require water obtain it then. The bell-glasses must not be replaced until the water has drained off the cuttings. When struck, the bell-glasses are removed and the plantlets are gradually hardened off. After they have made about half an inch of new growth they are topped with scissors.

FIRST POTTING.—This is done in spring when the cutting-pots are shaken out and the plants placed three in a pot. The pots used are small, known here as thumbs (two and a half inches), and the soil is a mixture of dark peat and sand, equal parts of each. When potted the plants are placed in frames and kept close and shaded for a few days. After twelve months in trios, as above, the plants are ready for removal into separate pots. These are thumbs, as be-

fore; the soil used is the same as before, but less sandy. It is a good plan to stake the plants before they are shifted, a stout deal-stake five inches long being given to each. When potted, place the plants back in the frame. Pinch out the tips of the shoots again after a little growth has been made.

FINAL POTTING.—If the treatment hitherto has been right the plants ought now to be sturdy little bushes with from eight to a dozen short shoots and a thick net of white roots. In December or January they may be potted into four or five inch pots. The soil must not be of the light brown character, such as is used for Orchids, but good black-brown heather-peat. It should be broken up roughly and mixed with silver sand. In potting the soil should be pressed down firmly with the hand. Potting-sticks should not be used. The frames are still the most suitable place for the plants, where they must remain till the middle of June, when they may be placed in the open. A position exposed to full sunshine all day is indispensable. Beds, say, four feet wide, formed of ashes, are best, the plants to be stood upon or half-plunged in the ashes.

TEMPERATURE.—This Heath dislikes artificial heat. If frost can be kept from it by protection, and if light can be given occasionally in severe weather, the plants will be much healthier than if fire-heat is used. At Clapton the Heath-frames are made of wood, span in shape, eight feet across, four feet high in the middle, with movable lights; a two and a half inch hot-water pipe runs once round the frame. The lights are removed when the weather is not cold, even in midwinter, except for a few weeks after re-potting. Mats are thrown over the frames in severe weather. The golden rule to be observed is that fire-heat and a close atmosphere are distasteful to this Heath, and that sunshine and plenty of fresh air are its glory.

WATER.—Don't water a Heath till it is dry, and then soak it, is the maxim with growers of these plants. Absolute dryness, however, is dangerous, and often fatal. The plants should not be allowed to "flag." In very dry weather it is advisable to look over the beds twice a day, watering those that are dry only. Manures, such as nitrate or soot, are given when the plants are in vigorous growth. Be careful in the use of stimulants, or the result will be strong shoots, but all "blind" in respect of flowers. Beside the type we have two varieties—namely, *superba*, larger-flowered, and *alba*, paler in color.

New or Little-known Plants.

Clematis brevicaudata.

THIS pretty Asiatic species, figured on page 139 of this issue, is a decided acquisition to the climbing autumn-flowering plants which can be cultivated in northern gardens. Botanically it is closely related to the familiar Virgin's Bower of our eastern meadows, and, like that species, belongs to the section *Flammula* of the genus, distinguished by cymosely paniced, diœcious, apetalous flowers with white spreading petaloid sepals and stout blunt anthers. It is a graceful plant with slender stems climbing ten or twelve feet high, puberulous, dark green, ternately divided leaves, their divisions long-stalked and divided into three ovate-acute leaflets sharply and deeply cut above the middle, entire and gradually rounded at the base, or three-lobed, and sometimes almost entire. The flowers are produced in ample pubescent panicles rather shorter than the leaves, and open during the first half of September; those of the pistillate plants are followed by abundant showy fruit with bright brown akenes covered with pale hairs and slender plumose tails.

Clematis brevicaudata was sent to the Arnold Arboretum from the Museum d'Histoire Naturelle, in Paris, in 1886; in the same year seeds were sent to the Arboretum by Professor Brooks, of the Agricultural College at Sapparo, in Japan, which have produced the same plant, although this species does not appear to have been found before in Japan. It

has also come to the Arboretum from the Spath Nursery, at Berlin, under the name of *Clematis paniculata*.

It flowers regularly every year in the Arboretum, and usually ripens an abundant crop of fruit early in October.

Our illustration is made from a drawing taken by Mr. Faxon from one of the plants in the Arboretum.*

Cultural Department.

Should Farmers raise their own Vegetable Seeds?

UNDER the above title, in the Report for 1889 of the Pennsylvania Experiment Station, is given the result of one year's observations upon this question. No subsequent report

practice is generally attended with the complaint that the varieties are not as good as they were originally. It is true that the fruits taken for seed are not carefully selected, and they are not gathered until the plants are past their prime condition. A careful seed-grower will, however, take the best fruits only, which practice tends to the improvement of varieties rather than their degeneration. Again, the farmer does not give the same careful cultivation to his vegetables, nor is he likely to have as rich a soil as the commercial seed-grower is certain to choose for that purpose. The subject seems worth some attention. The following is quoted from the first report:

"The question in its scientific aspect presents itself in the following form: Are seeds which have matured under high cultivation (as on our best seed-farms) better for our less enriched farm-soils than seeds which have matured in these poorer soils? The answer must be found in a comparison of

Fig. 22.—*Clematis brevicaudata*.—See page 138.

has been made, although the experiment has been carefully continued upon the same basis. It is a somewhat common practice among farmers to "save seeds" from the vegetable-garden of such plants as seed readily the first year, and the

* *Clematis brevicaudata* was described when it first flowered in America as *Clematis Picroi*, another Asiatic species, GARDEN AND FOREST, 1, 357.

results regarding earliness, productiveness, vigor and quality of the products. The conditions at the station are favorable to the work, and last year seeds were gathered from the best of those vegetables that seeded. The ground in which they grew is not a rich garden-soil, but only an ordinary farm-soil. These seeds were planted this year (1889) along with seeds of the same

varieties from the seed houses of Landreth, Dreer, Thorburn and others. In March the seeds were examined and careful weights taken of one hundred seeds of each variety. It appears from the tables that in nearly all the varieties of Tomatoes and Radishes mentioned the station-grown seeds were heavier than those from the seed houses, while those of the Lettuces in the majority of cases were lighter. Following this examination a test of the germinative values was made by putting one hundred seeds of each variety in the germinators. These results, given in the tables under the heading 'percent. sprouted,' are slightly in favor of the station seeds in case of Radishes, but against them in that of the Tomatoes."

The tables referred to contain all the observations made upon the plants during the growing season. It did not seem wise to draw conclusions from the records of one season, knowing how variable individuals are apt to be. The strongest indications of the tables were noted at that time as follows: "(1) The station seeds were, as a rule, heavier than the purchased seeds. (2) The weight was no indication of the germinative value of the seeds. (3) In the majority of cases the earlier marketable products were obtained from purchased seeds. (4) The greater yield, with but few exceptions, was obtained from purchased seeds. (5) Lettuce from purchased seeds produced heads that did not shoot up to flower as early as the plants from station seeds. (6) Radishes from purchased seeds were larger, more tender and more uniform than those from station seeds. (7) On the whole the results are strongly in favor of seeds from good soil, however rich that may be."

Some of these indications have been so strongly corroborated by subsequent investigations that we are tempted to name them conclusions. The germinative value of the seeds was generally higher with the station-grown seeds as tested in the germinators, but as many germinating seeds fail to vegetate in the soil, an experiment was made to test the relative values as to this point last year. It will suffice here to give the figures of the Tomatoes only, as they are emphatic on this point, and their behavior throughout is to be preferred in this discussion, since we must consider individual plants. The ultimate regard of the Radish is for the root, and of the Lettuce is for the head, while of the Tomato it is for the fruit, thereby implicating both root and stem in the production of the fruit. The following figures show that, with but two exceptions, the station seeds possessed the highest vegetative power. Seeds were sown in shallow boxes filled with good soil March 14th, and again March 25th of the following varieties of Tomatoes, using one hundred seeds of each variety, and noting carefully all that developed into good plantlets:

TOMATOES.	March 14th.		March 25th.	
	Landreth.	Station.	Landreth.	Station.
Acme.....	41	50
Golden Trophy.....	30	25	38	40
Livingston's Beauty.....	38	36
" Perfection.....	20	60	16	48
Mikado.....	45	80
Paragon.....	21	37
Trophy.....	25	21	20	50

These figures are, indeed, very much one-sided, but they concern a point of no serious moment to either the gardener or farmer. Seeds are cheap, and he can afford to sow three or four seeds to get one plant. Success in growing small plants from seeds depends largely upon the kind of care they receive. Thus would he dismiss the question. But what about the yield of marketable fruit? The third indication was strongly emphasized in the results of 1890 and 1891—namely, that "in the majority of cases the earlier marketable products were obtained from purchased seeds." The plants were all treated alike, in the hot-bed and in the field; yet, with but few exceptions, those from purchased seeds each year blossomed earlier by several days. In 1890 six out of seven parallels of as many varieties ripened earlier fruit by several days on plants from purchased seeds, and in 1891 five out of seven parallels indicate a similar result. Earliness is a matter of great moment to the market-gardener, because of the better prices obtained for first fruits.

A most peculiar coincidence lies in the fact that in almost every instance the heavier yield is associated with the later-appearing fruit, and is almost always with the plants from station-grown seeds. Thus:

Golden Trophy—Purchased seed, first ripe fruit July 30th; total yield of three plants up to time of frost, 11,143 grammes.

Golden Trophy—Station seeds, first fruit August 5th; total yield, 14,809 grammes.

Livingston's Perfection—Purchased seed, first fruit July 27th; total yield, 19,255 grammes.

Livingston's Perfection—Station seed, first fruit August 7th; total yield, 29,170 grammes.

In point of yield, therefore, the above figures (which are only representative cases from records) rather tend to favoring station-grown seeds, although the reverse seems to have been the indication for the first year. In a careful comparison of individual fruits it was found that the tomatoes from station seed attained a greater average weight and size and were generally possessed of thicker walls and more flesh throughout.

It should be added that the seeds used in every year of this experiment were taken from the original packages. Therefore the influence of climate upon the production of the seed is practically a fixed quantity, and the ages of the seeds remain relatively the same.

Thus far in the experiment two important conclusions seem to be strongly warranted by facts and figures regarding tomatoes:

1. Plants from purchased seeds yield earlier fruit than those from home-grown seeds.
2. Plants from home-grown seeds produce more abundantly than those from purchased seeds.

The Greenhouse Under Trial.

WHEN arranging the greenhouse, the details of which were given in this journal (vol. v., p. 6), there was some doubt as to whether the two sections could be preserved in practical independence. It will be remembered that the design was to provide an intermediate house with a temperature of fifty degrees, and a cool section with a temperature of thirty-five to forty degrees, united under the same roof and partly open to each other. To provide comfortable quarters for a variety of plants is always a problem to the amateur whose taste takes anything like a free range. The greenhouse-plants are not especially difficult to arrange, for even in a small house one can usually find a suitable place for tender ones, but to arrange for those which must be wintered at a low temperature ranging to just above the frost-line is not so easily managed. The warm section has been rather improved by the change, being made more airy, while the temperature at night has been readily kept at from fifty to sixty degrees. When the north wall has been raised about three feet and steps have taken the place of the present north bench, I cannot at present see how any further arrangement could add available plant-room in the space. The annex has shown more vagaries of temperature, as this has been more influenced by outside weather, but during cold nights there is usually an extreme difference of twenty degrees in the two sections. The cool end of the annex is usually forty degrees and under, and the thermometer has often registered thirty-two degrees there.

This has been a good place to store Auriculas and other plants which should be kept nearly or quite dormant. As a matter of fact, this end was full of dormant plants, while within a dozen feet Cattleyas were brought into bloom; this, it will be remembered, with no partition between. The difference of elevation will, of course, account for a large portion of difference in temperature of the unheated section. As the door of the furnace-room is opened at night the end nearest this is the warmest, but this warmth does not make much impression on the solid bed. This bed is on the level of the garden, and the water from outside works up from below, keeping it cool, so that Carnations, Roses and Pansies planted out have made very little progress. Unless some arrangement was made for draining this bed thoroughly or for keeping the water out, it would probably become sour and unfit for use for planting out, and it would be better in any event to use it as a bed for plunging plants in pots. Pansies, Violets and Carnations, in pots, would be happy there. It has proved a capital cool bottom on which to stand pots of bulbs to come forward gradually, the flowers from these being much better and more lasting than if brought forward in more warmth. Some shelves near the sash furnish convenient places to arrange the pots when plants are in flower, or to store those which are averse to moisture. The bed being very wide the outer edge is used for the storage of Chrysanthemums which have come on slowly. At present a few Genistas, Azaleas and Easter Lilies, in pots, are slowly making ready to expand their flowers for the Easter-season. These latter, however, require rather more heat, and, after being well started, are properly brought forward in the warmer house.

While the expansion of the house has doubled its capacity and given the greater range of temperature, the necessary care has increased very little beyond the oversight of more plants. But as most of these were formerly relegated to a cold frame, the care has been actually less than before. The fire has been no more care, while the cool house during the winter requires very infrequent waterings. Of course, no one could devise a greenhouse which would be entirely satisfactory to another, and these details of some experiments are offered only as suggestions, which may possibly be helpful to persons with requirements somewhat similar to mine—i. e., a small house, with a wide range of temperature, which need not be a great care.

Elizabeth, N. J.

J. N. Gerard.

The Flower-garden.

IN the best gardens it is found that hardy perennials alone are not as satisfactory as when plants of other characters are judiciously mingled with the permanent occupants of the border. Many hardy plants flower early and die down at midsummer, and something must be provided to take their place, if for no other purpose than to cover the ground for the remainder of the season. The easiest way to do this is to sow, or plant, annuals in the vacant spaces, to fill up the gaps, and perhaps to render other services which we have not taken into account. On this side of the Atlantic we have as yet heard nothing of the dread disease that attacks Narcissus-bulbs, known as basal-rot. No doubt our drier summers, which prevent superfluous moisture around the bulbs during the resting period, enable them to enjoy a marked season of rest after the foliage begins to die down. To do this, European growers sometimes have to lift their stock of certain kinds to ensure thorough ripening and complete rest, and American cultivators sometimes ask if it is necessary to lift the bulbs annually, the impression that it is being probably derived from foreign periodicals and practice. It has never seemed to me essential to lift any bulbs except for purposes of division; and perhaps on retentive soils, which hold considerable moisture even in dry weather, the planting of annuals over them may have an excellent effect by appropriating this surplus water and such nutriment as the bulbs are unable to assimilate when at rest. Last year China Asters proved a complete success over the Narcissus-bulbs, the latter commencing to make new roots when the heavy fall rains came that put an end to the Asters.

The basal-rot is, unfortunately, only too common here among certain species of Lilies. When lifting a refractory kind we have too often seen it tumble apart, leaving but a few of the inner scales adhering to the root-stock. *Lilium excelsum*, *L. Brownii*, *L. Pyrenaicum* and the non-rhizomiferous Californian species are well-known instances, as too many of us can testify. This disintegration must not be confounded with the Lily disease proper, which is quite another thing. If planters would try these delicate Lilies among other plants, even among the dwarf shrubs, where they would have to fight more or less for an existence, the results would be far more satisfactory. I have seen *L. Pyrenaicum* (a most refractory kind) naturalized among rank grass, holding its own year after year and filling the air with its fragrance. Lilies are not exacting in their demands, and I think we usually err in kindness to them. We give them rich soil when decayed leaf-mold would be better, and we keep the soil about them religiously free from plants that would shade the surface of the soil, and keep it moist in hot weather, and absorb by root-action any superabundance of moisture when the bulbs are resting.

Besides strictly bulbous plants there are many herbaceous ones which die down early, such as the beautiful *Corydalis nobilis*, so rarely seen in gardens; *Mertensia Virginica*, the Oriental Poppies, all *Trilliums*, some of the *Dicentras* and *Ranunculus*. With a little forethought and less trouble, at least two distinct effects should be obtained in a border planted with hardy plants. The plants to use will readily occur to those who wish to try the plan;—Asters, Zinnias, Stocks, Mignonette, Candytuft, annual Poppies and Larkspurs, with such summer-flowering bulbs as *Gladiolus*, *Tigridias*, *Milla biflora*, *Tritomas* and *Montbretias*, these latter being lifted and stored in the cellar in fall.

South Lancaster, Mass.

E. O. Orpel.

Petunia Blight.—In a large commercial propagating-house it was lately observed that many of the *Petunias* in small pots looked yellow and unhealthy. A microscopic examination of the diseased leaves proved that they were infested with a genuine leaf-spot fungus (*Ascochyta Petuniæ*). Frequently the leaf is attacked near its centre and the fungus spreads rapidly

in all directions, often in such a way as to exhibit a number of well-defined rings in the infested area. The spores are produced in vast numbers in spherical bodies, each with a small opening at the middle of the exposed side, and from which the spores stream in a serpent-like coil when a dry leaf is placed in water. Examination of other dead leaves showed a second fungus, differing in several respects from the *Ascochyta*, but in nothing more than in the spores. These, instead of being of the shape of a figure 8, are long and slender, often somewhat curved. This offender is a *Septoria*, which seems to be new, and it is likely to wear the name of *S. Petuniæ*. Both of these fungal enemies were doubtless in the stock plants from which the cuttings were taken, and a large part of the difficulty would be obviated by using healthy mother plants. From the nature of the troubles it is evident that the diseases could be held in check by the standard fungicides if taken in time.

Rutgers College.

Byron D. Halsted.

Success with Lilies.—The largest and finest bulbs of *Lilium superbum* I ever found were growing in a reclaimed swamp which had been drained to a moderate depth and planted to Cranberries. The Cranberries failed, and wild grasses and bog-plants were allowed to take their places. The Lilies originally grew in the muck, of which there was a good depth, and this had been covered with about three inches of sand, making in all about six inches of covering, and they were thickly shaded by a rank growth of grass. The largest single bulb of this Lily I ever found was growing by the road-side, where the wash of the road had covered it deeply with coarse sand. This bulb had an immense system of strong roots, and both bulb and roots had that clean white appearance which indicates a rapid and healthy growth. To all appearance this plant had nothing but wet sand to sustain it, but no doubt the washings of the road furnished it with liquid-manure in just that dilute form which best suited it. The best-cultivated Lilies are grown under similar conditions. If a deep furrow is run through well-drained sandy land, and swamp-muck is liberally placed in the bottom, with a light covering of sand, the bulbs can be set on this and the furrow filled in. With a liberal mulch of sphagnum over this the Lilies can hardly fail.

Hammon, N. J.

Correspondence.

Spring's Onset.

To the Editor of GARDEN AND FOREST :

Sir,—Those who watch the outdoor world observed a strange event this year in the sudden arrival of spring. Commonly we are used to some faint and broken preludings of the real season—advances, arrests, retreats. This year there were none of these. The winter has been nearly normal, and showed no fantastic outbreaks of vegetation due to unwontedly mild weather. The Japan Quinces, indeed, threw out here and there a blossom in midwinter, but we are used to these sportive reminders—signs of nothing but a hardy, happy habit. The Willows, before the new year, had wrapped themselves in aureoles of deeper tint than their accustomed winter adorning, but they kept their dull gold unchanged. Such, at least, was our observation on the island of Manhattan, and especially in its noble pleasure-ground, the Central Park, "which," the London *Spectator* has just said, "in another generation will be the most beautiful public resort in the world," the *Spectator* not knowing nor dreaming of the possibility that anybody should plot to convert it into a trotting-course.

On one day the park lay in still winter guise, the guise of February certainly, and not of December—for there is a difference—but distinctly of winter, silent, in a monotony of color. The next morning spring had come, the monotony was broken, the land and all its children stirred and stretched with awakening strength. The "furtive look" had come, the mark of "a purple finger on the slope," the feeling of "a flower expected everywhere," to use Emily Dickinson's phrase. Stems of shrubs were dyed suddenly with brilliant carmine or vivid green. Masses that only the day before had been dull brown across their tops were now suffused with pale pure yellow, difficult to fix as the end of a rainbow, vanishing under close inspection, but from a distance positive and distinct. So had a glow come into the gold of Willows, and the massed tree-tops seen across open spaces and against the sky, soft, deep rose-purple in place of sepia. All this, and much more, actually overnight, if close observation day by day may be trusted. And though such changes are subtle they are unmistakable, and essentially greater than many of larger physical proportions, for they are of character.

Every season we are apt to esteem peculiar, in spite of inexorable records that show general and particular likeness, and it may be unwise to insist too strongly upon the absolute novelty of sudden change such as is here recounted, but in the memory and records of one observer it stands alone. Whenever this change does come, and whether gradually or suddenly, it is one of the most affecting beauties of all the year. The mist of tender color is more enchanting than the gorgeous beauty of which it is the prophecy. And it is not only in itself beautiful, but a marvel and a mystery—a mere hovering haze that flies before one and evades approach; ghost-like, as though it were the spiritual part of flowers first arrived, and waiting uneasily for bodies yet to be.

New York.

J. E. Learned.

A Freak of a New England Orchid.

To the Editor of GARDEN AND FOREST:

Sir,—It was on the first day of August, in the course of an idle tramp of an hour or so, in the midst of a shady mosquito-haunted bog, where the smaller purple-fringed Orchids were blooming in abundance, that I was almost electrified by the sight of a stately spike of brilliantly white flowers just before me. With the eagerness of an amateur botanist I gathered this solitary specimen, jumping at the conclusion, as usual in such cases, that it was certainly something never before reported in this locality. On examination, it bore a rather humiliating resemblance to the *Habenaria psychodes*, in whose company it was found; but the height—two feet nine inches—and length and diameter of the spike far exceeded those of any of its humble relatives. It was a magnificent specimen, in perfect flower, and the petals and sepals were certainly larger than those of any of the orthodox *H. psychodes*. Then, too, the lip was in a horizontal position, at right angles with the erect upper petals. With these exceptions, the flower was identical, even in odor. It is to be remembered, of course, that it was pure white.

The question is, What was it? If the fringing of the lip had only been capillary and the spike a little looser, it would have passed for *H. leucophæa*, as described in Gray's Manual. I am told by good authorities that the fact that it was white counts for nothing, and the fact that it was growing in company with *H. psychodes* is presumptive evidence that it was simply an albino of that species. Other good authorities say that, while this is the natural supposition, it is possible that it is a hybrid—perhaps of *H. lacera* and *H. psychodes*. I have seen white *Pogonias*, heard of white *Cypripediums* (acaule), but never heard of a white *Habenaria psychodes*. Of course, they are found in deeper and lighter shades of purple, but has anybody ever found one pure white?

Norwich, Conn.

Periodical Literature.

In a paper recently read before the Torrey Botanical Club, in this city, and reprinted in the *Bulletin* of the club for March, Professor Byron D. Halsted says that during the past two years a large number of variegated plants have been examined with reference to the presence of parasitic fungi, attention having first been called to the subject "by a study of the foliage of a variegated Ash, which had its leaves badly spotted with a species of *Coniothyrium*, while ordinary Ash-trees were free from the same fungus." He gives an alphabetical list of fifty genera, including more than a hundred species of variegated plants, both hardy and grown under glass, which had been found specially subject to the attacks of fungi. The author says that it is not his purpose to enter into the causes of etiolation or variegation, or to draw well-defined conclusions from the facts which he presents. But he adds that the ordinary green forms of many species have also been studied, with the result of showing that they are much less frequently attacked than the variegated sorts. Furthermore, in some plants the etiolated part occupies large portions of the leaf, and, as a rule, the portions without the chlorophyll are the most susceptible. In the *Aspidistra*, for example, the one-half of the long leaf may be green and the other white, in which case the latter is with few exceptions the only one attacked. In the *Hydrangea* the middle of the leaf is etiolated, and here the blight first begins its destructive work. In other plants, where the white is distributed in blotches near the margin of the leaf, the decay due to the fungus produces a ragged edge. And when the variegation is quite evenly distributed over the leaf the parasite is widely scattered and the whole leaf decays, as in *Dieffenbachia* and *Abutilon*. The author concludes: "There seems to be no question that the variegated leaves are more suscep-

tible to parasitic fungi, and that likewise the etiolated parts are the ones first attacked. The absence of green in a leaf is a source of weakness. Speaking generally, a variegated plant lacks capacity for the best work, and the gardener, in propagating a variegation, no matter how it may have originated, is propagating a weakened plant in so far as it has had its normal amount of chlorophyll reduced. It is a pity that so many of our choicest variegated plants blight easily; it is, however, natural that they should do so. Even a fungus parasite will take the line of least resistance."

We may add to this interesting communication that it does not seem a great pity that variegated-leaved plants should have characteristics which may gradually discourage that love for them which is so marked among amateur horticulturists, and, unfortunately, among some landscape-gardeners as well. Except as curiosities to be preserved in a greenhouse or used in the decoration of a room, variegated forms are seldom as attractive as the more normal forms from which they have originated, or, we may truthfully say, deteriorated; and their excessive use out-of-doors is one of the evils against which true lovers of landscape beauty have to protest. In formal gardening arrangements a discreet taste can employ them with good effect; but in the naturalistic arrangements, which are much more common in the present day, very discreet, indeed, must be the taste which can use them without injury to the repose, harmony, unity and simplicity that should characterize a landscape. In most European countries they are still more profusely employed than here; but even here we too often see lawns and plantations disfigured with many crude spots of variegated color where the eye would be far better pleased by the gentler variety which different shades of green can give.

Recent Publications.

The Formal Garden in England. By Reginald Blomfield and F. Inigo Thomas. London: Macmillan & Co., 1892.

There has long been great need of a good book in the English language on formal gardening. The one which Mr. Blomfield has recently written, and which Mr. Thomas has illustrated, is interesting, and in certain respects is instructive; but it will not adequately fill the empty place on our shelves. It will do little to convince narrow devotees of the "natural style" of gardening that the formal style has its merits also, and still less to explain to those who already believe this fact under what conditions each style is appropriate, or even what is the essential difference between them. This is because its author has written not in an impartial spirit, or even as a fair-minded advocate. He stoutly denies that there is or ever has been such an art as landscape-gardening, and implies that in the nature of things there can be no such art. Formal gardens, he says, are designed; grounds treated in other ways are not designed, and only make a pretense of being designed. He condemns the narrowness of landscape-gardeners, and proves himself narrower than any of them. He carefully notes their follies in act and word, but as carefully abstains from any mention of their worthy work or even of the problems which afford them their best opportunities. He perpetually goes out of his way to assert that landscape-gardeners have ruined whatever they have touched, but he never explains how their larger undertakings might be better managed. The only passage in his book which even grudgingly admits that the landscape-gardener as well as the designer of formal gardens has his place in the world, is the one where, after saying that formal gardens do not need to be very large, he adds, "If either style wants room, it is the landscape, for unrestricted space is of the essence of natural scenery; and, indeed, the only places where its use appears tolerable are gardens such as those of Chatsworth, where the grounds are so large that there is a real suggestion of scenery *sui generis*, as of a wood in which clearings have been made and the grass kept carefully trimmed." In short, Mr. Blomfield's preferences are so narrow, his temper toward everybody and everything unapproved by these preferences so bitter, his arguments so one-sided, and his descriptions of the aims and ideas of the landscape-gardener so disingenuous, that his book is likely to do more harm than good to the cause which he has so warmly at heart. He could have pleaded the cause of formal gardening design much more effectively had he shown us first where and how landscape-gardening can produce good results and then where and how it cannot, instead of assuming that it has never produced a really good result, and in the nature of things never can.

The historical passages of his book are interesting when one can ignore the writer's underlying mood. They give in a compact shape a great deal of information hitherto scattered

through books which are inaccessible to the general reader. The illustrations add greatly to the value of the text, although they do not always prove its assertions. They seem to show that English gardens, before French influence had extended them into parks and planted them with dense groves and mighty avenues of long extent, must have been pretty spots to look at, excellent spots in which to grow pretty flowers, and good accompaniments for architectural effect to the houses which face upon them; but that the excellence in design, of which we read so much, was of a very rudimentary and naïve sort except as regarded absolutely architectural features. Terraces and walls appear to have been well imagined and constructed, but nothing that can be called an architectural treatment of trees and of large areas of water and grass appears to have been attempted until the advent of French fashions. The garden areas themselves were small, and their design consisted simply in the perpetual repetition of the simplest geometrical figures. They were undoubtedly good gardens, and gardens of the sort which were most appropriate to houses of the usual English kinds. But they were not great works of art like the gardens of Le Nôtre and his immediate followers. Mr. Blomfield's chapters are a little confused in arrangement, and it is not always easy to put the right date upon the things which he describes; but the general impression left by his book is that the advent of French influence first developed garden design in England into an important art. Best of all are the chapters which discuss in succession the different features of old gardens, and here we often come upon very good bits of advice. For example, the author wisely counsels the use of stone or leaden statues and ornaments instead of white marble ones, which are too glaring for the English climate, and bronze ones, which are too sumptuous in effect except amid very splendid surroundings. He is right, too, when he says that clipped shrubs and trees are not more unnatural than many other things which we admit into our natural gardens, although he exaggerates in saying that they are as natural as clipped grass. The ordinary processes of husbandry and pasturage have accustomed our eyes to surfaces where the grass is cropped short, but not to trees cut into stiffly symmetrical forms. Such trees may have their place in art, however, and we only wish that Mr. Blomfield had defined this place more intelligently for the instruction of those who deny that it exists. We wish also that, while protesting against that degeneracy in topiary work which followed the introduction of Dutch gardening fashions, he had not himself chosen to admire one very Dutch example of which he gives an illustration. Trees and shrubs may be clipped upon occasion, but never into the likeness of a wall upon which are perched two colossal doves. Nor will all the architectural and sculptural features of old gardens which the illustrations reproduce ever gratify a taste that cares for purity in outlines and for vigor combined with delicacy in the treatment of details.

In speaking of grass-theatres Mr. Blomfield cites no existing example, but says that "in the gardens of the Prince Bishops, of Wurzburg, there was a famous amphitheatre formed of banks of turf with clipped hedges for scenery." He may be interested to learn that in the Grosse Garten, at Dresden, once a royal but now a public park, such a theatre still exists in good preservation. It lies between two of the main avenues, hidden from sight by thick masses of trees, and is approached by a narrow path. This path cuts it through the centre, the ranges of turf-seats rising on one hand and the turfed stage on the other, surrounded by masses of foliage, which were probably once more closely trimmed than they are to-day, and ornamented with moss-grown statues of gray stone—Rococo works, which are pretty bad from the sculptural, but very effective from the decorative point of view.

Chemicals and Clover. This is a little pamphlet by H. W. Collingwood, one of the editors of the *Rural New Yorker*, and the part of it which has real value is that which records the success of certain New Jersey farmers who practice the following four-year rotation of crops: Potatoes are planted on ground where Corn has been grown the year before, with a thousand pounds of some so-called complete fertilizer to the acre sown broadcast before planting and five hundred or more pounds later in the drill. In the fall the Potato-ground is plowed and seeded with Wheat and Timothy, and Clover is sown in the spring. The next year the hay is gathered, and in the third year of the rotation, after the hay is cut, all the stable-manure made on the farm is hauled out and spread on the sod, and the aftermath is allowed to decay on the ground. Next spring the land is plowed and the ground planted to Corn, which finds abundant nourishment in the decaying sod. The principle of this sys-

tem is that the heavy dressing of chemicals on the Potatoes not only yields a profitable crop, but leaves the soil sufficiently fertile to give a crop of Wheat and Grass. The stable-manure helps to make a heavy sod, and the Corn is able to appropriate the coarser part of the food by its strong digestion. As little stock is kept as possible outside of the working teams, and no particular pains is taken to increase the amount of stable-manure. We apprehend, however, that there is little danger of having too much of this on the sod; and the stable-manure does not deserve the depreciating tone in which it is alluded to.

It is quite true that in many cases it is cheaper to purchase and apply a given amount of nitrogen, phosphoric acid and potash in commercial fertilizers than it is in stable-manure, and in some cases the same amount of these in chemical fertilizers will show quite as good results as it would in well-rotted stable-manure. In other cases in our own experience plant-food in chemicals has not been relished by crops as well as the same food in well-decayed and well-fined stable-manure. It may be that, apart from the plant-food in stable-manure, it furnishes a nidus wherein are multiplied those microscopic organisms which science has found to play so important a part in the growth of plants. Some old market-gardeners on Long Island will not haul stable-manure from the station to the farm if it were given to them. They say it is cheaper to buy chemicals and to apply them alone than it is to transport and apply the bulkier material. But, then, in these old gardens tons of manure have been used on every acre annually for a generation, until the ground is filled with carbonaceous matter left by old applications from the stable, so that the nitric ferment and other bacteria which are helpful to plant growth may already occupy the ground in sufficient numbers. This, however, is only a surmise, but the fact remains that our knowledge of the processes by which plants avail themselves of the materials for their development which are found in air and water is very limited. There is no doubt that so-called artificial fertilizers are destined to a wider use in the future as we learn how to use them to better advantage, and the accurate records of any experiments with them are always worth preserving.

Notes.

In Mr. Blomfield's *Formal Gardening in England* he tells us that during the War of Independence many of the leaden figures which ornamented old English gardens were exported to this country, nominally as works of art, but really to be melted down and cast into bullets.

In Ellwanger & Barry's general catalogue, in addition to the classified list of Roses, where the different families are separated with unusual care, there is a valuable alphabetical list including about 350 of the leading sorts in cultivation, in which the class to which each individual belongs is indicated by abbreviations.

Last week Mr. Gerard sent to this office flowers of *Iris Bakeriana* and of *I. histrioides* which had been snowed under twice. In spite of the severe weather, they looked perfectly fresh and bright, and exhaled a distinct Violet odor. These early Irises are among the most attractive of the flowers which brave the frosts of March.

A Philadelphia correspondent of the *American Florist* says that Mr. C. D. Ball has remarkable success with *Lilium longiflorum*, which he grows in quantity for Easter decoration instead of *L. Harrisii*. The flower of the former has more body, so that it will endure longer, especially if it is warm, as it often is at Easter-time, while the erect habit of the flowers makes them easier to ship. Most persons consider it more graceful than the Bermuda Lily.

So careful are the Japanese in their study of what is appropriate and inappropriate in the arrangement of flowers, that they would not use even a small metal stem-fastener without considering the character of its design. A fastener in the shape of a frog, for instance, may be used with both land and water plants, but one in the shape of a hare, especially suitable for use with wild plants and grasses, would never be affixed to water plants, and one in the shape of a pair of carps is reserved for water plants alone.

The exhibition of the Pennsylvania Horticultural Society next week promises to be one of exceptional interest. The large private collections in Philadelphia and its neighborhood are always represented by choice plants, and the local commercial growers have an enterprise and public spirit which is seen at its best at these exhibitions. Mr. Blanc will make such a

display of Cacti as can be seen nowhere else in this country, and a feature of great interest will be a contest for the premium offered for Mushrooms.

The last bulletin from the South Dakota Agricultural College Station relates to the growing of the Sugar Beet, and it is stated that with proper cultivation these Beets, with a high percentage of sugar, a good purity co-efficient, a large yield per acre, and in every way adapted for the manufacture of sugar, can be grown throughout the greater portion of that state. A report from the Experiment Station of Wyoming also adds that the dry cool autumn of the arid region there tends to store sugar in the beets, which will grow well where a slight summer irrigation can be given to the crop in a mellow soil.

A new Violet, burdened with the name of Frau Hof Garten-direktor Jülke, and said to be a cross between Lee's Queen Victoria Violet and *V. Rossica superba*, was introduced a year ago by a German florist. The *Gardeners' Chronicle* quotes some Continental authority who pronounces this the pearl of all existing varieties. It is not furnished with runners, and the leaves are of a glittering green color, which is a particular merit. The flower-stalk is long, the flowers larger than those of the Russian, the color light blue, the fragrance powerful, and in floriferousness it exceeds all other known Violets. Placed in the greenhouse or in a cold frame in the autumn, it continues to bloom, and if at the end of the month of December or beginning of the new year it can have the warmth of an intermediate house, its season of flowering will be extended into the spring. The cultivation of the plant is identical with that commonly pursued with Violets.

The notorious Italian slum in this city, which is called Mulberry Bend, will be torn down shortly, and the space it covers will form part of a new park, consisting of an irregular plot bounded by Park, Mulberry, Bayard and Baxter streets. Baxter Bend, an equally ill-favored quarter, will also disappear, and the new park will touch the corner of that little triangular breathing-space which was established when the Five Points district was partially redeemed some years ago, and which surely bears the most oddly optimistic name of any such spot in the world—Paradise Park. The price which the city will have to pay for the new park will be very large, for land upon which so many human beings are crowded commands at least ten dollars a square foot, and often more than twice that amount; but no money will be wasted if it insures another playground for the very poor, and at the same time the destruction of the vilest rookeries which disgrace New York. And yet, with a strange inconsistency, while New York is spending a million and a half of money to make room for a little turf and a few trees here, some of her leading citizens are beseeching the Legislature for the privilege of covering up Bryant Park with a huge municipal building, others are trying to confiscate City Hall Park for the same purpose, and others still are endeavoring to destroy Central Park itself in the alleged interest of the American trotter.

At the last convention of the American Forestry Association Mr. Gifford Pinchot read a paper on the history of forest-policy, from which we quote the following: "The spirit of the recent Swiss forest-legislation is one which must permeate our own coming forest-laws if they are to win that acceptance with the people without which they must be worse than useless. It has been summarized as follows by Professor Landolt: 'Our forest-laws are intended to work more through instruction, good example and encouragement than by severe regulations. This method is somewhat slower than one which should involve more drastic measures, but the results achieved are more useful and lasting. When forest-proprietors do something because they are convinced of its utility, it is done well and with an eye to the future; but what they do under compulsion is done carelessly and neglected at the first opportunity. What they have come to learn in this way, and have recognized as good, will be carried out, and that better and better from year to year.' This homely statement of the great Swiss forester is full of the wise moderation of a man conscious of the dignity of his work. Successful forest-reform, here as there, must be a growth from the education of the people, finding its expression in laws which respect both the needs of the forest and the needs of the people, and which waste no time in mistakes. Such legislation is respected, because it is capable of being enforced. The results of it are so large, it is so surely a part of the future, that the friends of forestry in America ought to work for it with the steady vigor of men who know they are going to win."

An account of that district of southern France which is called the Camargue, recently published in the *Revue Indus-*

trielle, shows how extensive and how successful are the works of irrigation undertaken by the French Government. This district occupies the triangular space formed by the two branches of the Rhone in their course between the point of forking and the Mediterranean, and although in mediæval years it contained important seaport-towns, for generations it has been a malarious waste, where the ancient cities presented astonishing pictures of death and decay, and where the boundless fields were given over to wandering herds of half-savage cattle. The district being really an island, composed entirely of alluvium brought down by the river, it was often partly overflowed; so the first need was to build dykes to protect it. Then ditches were dug and pumps set up for the removal of the water which soaked into the soil beneath the dykes, and this water was thrown into a great basin called the étang Valcarès, which was furnished with an outlet to the sea. Then, as the land would thus have been rendered too dry, irrigating canals and pumps were established to bring in water from the Rhone at the upper part of the territory, and as by this means certain portions could also be flooded if desired for the destruction of the phylloxera, large plantations of the Vine were made. The climate is excellent for grape-cultivation; pasturage also became profitable, and certain new plants, among them the Australian "Salt-bush," have been introduced with a prospect of commercial success. Thus, according to the *Revue*, a desert region dangerous to health has been transformed into a fertile stretch of country which is rapidly growing more and more populous, and a network of railways has been begun to develop its resources to the full.

In the last number of *Agricultural Science* there is an account of a new edible Blackberry, by Professor Bailey, which, in honor of Dr. C. F. Millspaugh, who collected it at an altitude of 3,500 feet in West Virginia something more than a year ago, is called *Rubus Millspaughii*. It is a bush Blackberry with long wand-like canes and destitute of thorns. Dr. Britton, who named it, knew of no other specimens than those of Millspaugh except a single leaf of it in Linnæus' Herbarium, in London, collected by Kalm more than a century ago. Professor Bailey thinks, however, that it is generally distributed over the northern and eastern states, since he has had good specimens of it from the Big Smoky Mountains, in North Carolina, at 6,000 feet altitude, and he knows of other specimens from the White Mountains, and the Keweenaw Peninsula, Lake Superior, so that it would appear that the species grows upon our northern borders and follows the mountains southward, which accounts for the fact that Kalm found the specimen in Canada. This Blackberry has some importance to horticulturists on account of its thornless canes. The so-called thornless Blackberries of gardens are nothing but comparatively unarmed forms of *Rubus villosus*. The fruit of this plant is said to be good. Mr. Kofoid, who collected it in North Carolina, writes that as late as August 29th the fruit was just ripening to a faint reddish tinge, and was quite palatable even then. The natives say that the fruit ripens in September. The berries are large, long, slender and sweet, lacking the acid and bitterish quality of berries on the lower mountains. Besides the absence of thorns, which distinguishes this species from *Rubus villosus*, it lacks the pubescent character of the common species, the leaves are thin, the leaflets sharply toothed and prominent; on vigorous shoots the leaflets are five, and the three upper ones have stalks from one to two inches long.

The Speedroad in Central Park.

IF the construction of a road for fast driving in Central Park was a matter of local importance merely, we should not feel called upon to make any further allusion to the subject. But the case is a representative one. All our rapidly growing cities feel just as New York does this pressure for more room. Land set apart for pleasure-grounds in these cities is constantly coveted by individuals and classes who wish to devote it to some special use which seems to them of pressing importance. Central Park was the first area of anything like a square mile in extent ever designed as a consistent work of landscape-art in the heart of a great city for purely rural recreation and the refreshing influence of pastoral scenery. If, after thirty years of experience, the leading city of the country should declare by its example that such a park could not be maintained for such a use, it would be a discouraging blow to all who take any practical interest in public pleasure-grounds in other cities. It would incite attacks on every other park and make all park-property in the country more insecure.

There is no need of restating the arguments against this project. Four years ago, when the last formidable movement for securing the so-called speedroad was in progress, the salient objections to it were set forth in this journal (Vol. 1., p. 37), and as late as our issue for March 9th the subject was discussed in a leading article. It may be well, however, to make a brief statement of what has recently taken place. Less than a fortnight ago the House of Assembly passed an act which had previously passed the Senate authorizing the construction of a road in the park for fast driving. The Governor signed it the same afternoon and the Mayor of this city gave a statement to the morning papers in approval of the measure. The Park Board at a special meeting the next day ordered their engineer to prepare plans for the road and voted funds to defray the expenses of the survey. Nearly every newspaper in the city

at once attacked the scheme and a volunteer committee of citizens was formed to invite petitions of remonstrance and secure funds for holding a public meeting. The demonstration was so prompt and energetic that the Mayor discovered a "difference of opinion" in the matter, and at his request the Park Board announced that it would give a public hearing on the question. The protestants appeared in force and the Park Board rescinded its action; and after the hearing had been continued another day, the Board voted that it was inexpedient to build the road. All this happened within a week. Meanwhile, names by the thousand and money enough to meet all expenses poured into the rooms of the Citizens' Committee. The newspapers kept up the attack with singular unanimity and vigor, and last Friday a memorable meeting to demand the repeal of the act was held in the hall of the Cooper Union. A committee of one hundred was then selected to lay the case before the legislature, and it is possible, though hardly probable, that the act will be repealed before this paper reaches its readers.

In large cities individuals are apt to feel indifferent about matters of this sort, so that the spontaneous uprising of the people was almost a surprise. Particularly gratifying was the action of the workmen, whose organizations lent most efficient aid to the defenders of the park. One of the most telling speeches at the meeting was made by Mr. Archibald, representing the Central Labor Union, who showed that the park had an especial value for the families of those who could not get away to the mountains and seaside for the summer. The sound views on the true functions of an urban park expressed by all the speakers at this mass meeting showed that the people are prepared to take high ground as to the value of such parks, and this is a renewed assurance of their safety. Ex-Mayor Hewitt was especially happy in demonstrating that a park is a great educational and moral as well as a sanitary influence in city life. A letter from Mr. Frederick Law Olmsted argued that since the earnings of the people of the city had been put into the park for a particular object it would be unjust and immoral to divert it to a use inconsistent with that object. The construction of the speed-track would, therefore, lessen the security of every man in the enjoyment of his earnings and tend directly to anarchy.

Altogether there is good reason to believe that the park is in less danger of any destructive invasion than it was before this attack. The people have had an opportunity to give expression to their affection for the park and to prove their power in protecting it. They have been called to think over their moral obligations in the matter, and the public-spirited men of the city, the men on whom its future prosperity depends, will give their influence to the side of stability and security when such questions arise, and will not permit the city to degenerate into a condition where nothing is sacred and nothing is safe.

A Modern Massachusetts Farm.

THE plan of an estate in North Beverly, Massachusetts, published on page 151, deserves the careful attention of all persons interested in rural economy because it stands for what we hold as the fundamental principle underlying all successful agriculture—the adaptation of the crop to the character of the soil. This principle is well understood now in most European countries, but the neglect of it in this has caused the unprofitable removal of millions of acres of valuable forests from lands suited by nature to produce forests, but entirely unfit for permanent and profitable tillage.

The estate which stretches along the western shore of Lake Wenham, a beautiful sheet of fresh water, consists of 275 acres, and was bought in 1879 by the late John C. Phillips, of Boston. The purchase comprised a number of farms or parts of farms and various small parcels of land; only a part of it, perhaps forty acres in all, being adapted

to tillage. A hundred acres of upland and swamp were covered with a natural growth of hard wood, Pines and Soft Maples, the remainder of the estate being overlaid by dry glacial drift, clothed with scanty herbage and occasional clumps of stunted Blackberry-bushes. Early attempts at cultivating this land had exhausted whatever fertility it had ever possessed, and the free range of cattle over it for generations had prevented trees from springing up to cover its naked surface and replace the forests of Pine which should never have been cleared from it.

The dwelling-house was placed by Mr. Olmsted, who was asked to prepare a scheme for laying out the estate, on a rough stone terrace built to receive it on the steep bank of the lake, and the drives as they appear on the plan were constructed under his directions. The beauty of the situation and the charm of the native woods on the sides of the old moraine in the north-eastern part of the estate had been the prime motives which induced Mr. Phillips to choose this particular site for his country home, but this once determined on it became necessary to develop some scheme for the economical treatment of the large area of poor land which could not be tilled except with large annual expenditures of money, and which could never be made into satisfactory and productive farming-land. It was evident that if the agricultural efforts of the owner could be confined to the good land that better results could be obtained than could possibly follow any effort to convert a larger part of the estate into a farm, and under Mr. Olmsted's advice this view was adopted. A tract of low, wet, rich soil, about forty acres in extent, in the north-west corner of the estate, and just north of the barns as they are now located, was thoroughly drained and made one of the best and most productive fields in Massachusetts. It remained to determine the destination of such portions of the remainder of the estate as were not already covered with trees. It was soon apparent that there was but one course to follow, and that was to cover it as rapidly as possible with such varieties of trees as grow naturally on poor soil, and so avoid the expense of annual tillage or the annual harvesting of unprofitable crops of scanty grass.

Mr. Olmsted's idea was to convert the whole estate, with the exception of the arable land in the north-west, into a more or less open forest, in the midst of which the manor-house should stand like a forest-lodge in an oasis of kept grounds confined to its immediate neighborhood and encircled by the boundaries of the terrace; and although this plan has not yet been entirely carried out, all the operations of late years have been made with the idea of gradually extending the plantations over the whole of the dry uplands. The first plantation was made in 1880, and the area now planted is about seventy-five acres. A number of varieties of trees were tried, principally European Larch, the Scotch Pine, the Austrian Pine, the Norway Spruce, the White Pine, the Douglas Fir and the Canoe Birch, but of late years White Pines have been used almost exclusively, about sixty thousand having been planted since 1883. The Larch has grown very rapidly, making trunks a foot in diameter in twelve years, and are as thrifty and as promising of long life on the shores of Lake Wenham as the Larch on Mr. Henry G. Russell's estate, described last year by one of our correspondents; they are not as tall, however, as the Canoe Birches, which have grown on this soil with remarkable vigor, indicating the value of this tree, one of the best timber-trees of our northern forests to plant on light gravelly soil. The Douglas Spruce has grown rapidly, too, and vigorously, and there is every indication that it will reach a large size on this soil. The Colorado variety of this noble tree, which is certainly one of the most promising of all exotic conifers introduced into the north Atlantic states, can be seen in greater numbers on the Phillips estate than anywhere else, different individuals displaying a remarkable diversity of habit and a great variety of shades of color. White Pines increase in height from one to four feet every year; and the appearance of the young plantations indicates that, for covering the

sterile hills of New England in spite of insects which attack and often deface it, this is the safest and the most profitable tree to plant.

We feel that an estate like this, managed intelligently on a system conceived and developed with the view to the best permanent economic results is an object-lesson of real public importance; any well-planned and prudently conducted experiment which directs public attention to the possibility and advantage of using lands not otherwise valuable in a way to secure a fair profit to their owner helps to establish and enlarge the prosperity of the state.

Here in America carefully prepared schemes for the improvement of country estates generally die with the person who makes them, and his efforts and expenditures are too often lost, but a better fate has attended the Phillips Place, which fortunately has passed into sympathetic hands, and is administered with intelligence, energy and steadiness of purpose, and with the determination to develop and perfect the well-considered plans of its original owner.

The Great Madroña of San Rafael.

SOME months ago there appeared in this journal (vol. iii., p. 509) an account of the California Madroña (*Arbutus Menziesii*), and a portrait of a fine specimen which had grown to a great height in the forests of northern California; in the present issue we are able to reproduce a photograph of the trunk and principal branches of the famous Madroña-tree which grows on the slopes of Mount Tamalpais, in the grounds surrounding the reservoir that supplies the town of San Rafael, in Marin County, with water. It is the largest of its race of which we have any record, one of the most marvelous trees now standing on this continent, and, from its position within the bounds of a carefully preserved piece of public property, one of the few really great trees of the country which may be expected to continue for many years to astonish and delight the lovers of nature and to live out its natural life. What the age of this tree is no one can conjecture; it has already attained a height of more than a hundred feet; the branches cover in one direction the span of seventy-five feet, and of ninety feet in the other direction, and the mighty trunk girths twenty-three feet at three feet above the surface of the ground.

For these measurements and for the admirable photograph from which the illustration has been made, we here offer our thanks to Mr. E. W. Woods, of Sancelito, California, an enthusiastic lover and student of trees.

Color in Rural Buildings.

THE use of color on the exterior of buildings is a subject to which in recent years American architects have given much attention. Foreign examples of strongly colored or polychrome work, both ancient and modern, have been seriously studied; the particular characteristics of our climate and atmosphere have been considered; and it has been recognized that in America, where the air is clearer and the light more intense than in northern Europe, very marked effects of exterior color can be used with good results.

The pale gray stone almost universally employed in Paris is admirably suited to local atmospheric conditions. Every painter knows that the atmosphere of northern France contains moisture enough to make a soft grayish envelope for all terrestrial objects, and to give the sky a soft and rather pale tone; and the so-called Caen stone of Paris is neither too white nor too dark to fit well into the scheme which the great colorist, Nature, has laid out. In Holland and England, where the air is still more moist, the deep red so commonly used for roofs is equally appropriate, coming out well against the heavy skies and harmonizing with the strong dark greens which much dampness produces in foliage and grass. But go to the south of France and to Spain and Italy, where the air is clearer, the light more forcible, and the sky bluer, and you will find that the best colors, and those most generally employed, are vivid yet light—chiefly whites and yellows, which, as a painter would say, have the same "value" as the clear bright greens of the

vegetation, the yellows and whites of the soil, and the blues and whites of the heaven. And in the roofs a clear, not heavy, shade of brown has generally replaced the deep red of northern countries—a tone which is not too pronounced to mate with the lighter ones, but is welcome among them as giving an accent of contrast and relief. If a bright red roof is wanted in a southern climate, it ought to be a bright light red—not the bright deep red of Holland, where a pale red would seem too weak for Nature's tones, and a clear brown would hardly tell in the landscape at all.

Our summers in the latitude of New York are as warm as those of southern France, and, indeed, New York actually lies in the latitude of Madrid and Rome. Our winters, of course, are very much colder; but atmospheric conditions do not change to correspond with isothermic lines; and all the year round, even in northern New England, we have vivid skies, a pellucid thin atmosphere and a clear bright scheme of natural color. Therefore, as our architects now know, the teaching of the south, not of the north, of Europe should be followed in the external coloring of our buildings.

Much has been done to improve and vary this coloring during the past ten or fifteen years. The streets of New York, for instance, are no longer given over to the dark brown sandstone and the strong red brick which used to rule supreme. Sandstones and limestones of paler colors, pale reddish, yellow and light brown bricks, and even bricks which are almost orange-colored, have been largely adopted, vastly to the increase of beauty of effect. In Boston a quite bright red sandstone is common, light brick is also much used, and Richardson's example has been often followed in the matter of polychromatic treatment. Of course, every result is not good; but we can note gradual growth toward true excellence in the color treatment of our city buildings; and, we are glad to say, white is again coming into favor for buildings in the country.

Once upon a time, of course, white was almost universally used in such buildings. They were almost always of wood, and whether they were simple box-like cottages, pillared Jeffersonian homes, or pseudo-classic or pseudo-Gothic churches, they were almost always given a coat of pure white paint. Then came a reaction, for which, we imagine, Downing was largely responsible. His admiration for English rural architecture was rightly very great, and his perception of the crudeness of such architecture in America was naturally keen. But in trying to reform the ways of his fellow-countrymen he did not realize that under different natural conditions different expedients are to be advised. Many chapters in his *Horticulturist*, and many pages in his books on rural building, are devoted to decrying the use of white paint. After his day we had a long reign of dismal hues—dark grays and sombre browns and dusky yellows—which, if they did not always painfully afflict the eye, did not give it pleasure or harmonize well with the surrounding colors of nature. Later there came a reaction, and in the days when villas were built in fantastic forms and profusely adorned by the jig-saw, bright hues of a wrong kind were applied, two or three, or even more, together, to add in tint to variety in form.

But it was soon felt that decidedly too much variety had been achieved, and another reaction came about. Painting was largely dispensed with; staining was substituted in a way which sometimes gave a pleasing and naturally mellow look, but sometimes revealed a mistaken desire to imitate the effects of age; or these effects were left to produce themselves: the shingles which were generally employed instead of the long-universal clapboards were left to "weather" into various tones of gray, and merely the trimmings and shutters of the house were painted.

These last-named practices are still pursued, but paint has come back again into greater favor, largely as a result of the liking for "Colonial" fashions of building in which clapboards are more appropriately used than shingles; and, owing to the same cause, as well as to a better understanding of the requirements of our atmosphere, clear light tones are generally preferred. We have come to see that our great-great-grandfathers were wiser than we once thought when they painted their stately Colonial houses a pure white or a pale yellow, and relieved them with trimmings and shutters of a darker color; and also that the farmer who had liked his cottage white, probably merely because it looked cleaner thus, was unwittingly more artistic than his descendant, who thought it more dignified and refined to live in a dark gray house with a deep red roof.

The natural tone which weathering gives to shingles of good quality is rarely inharmonious except where the air is strongly impregnated with salt, and portions of the house therefore get an almost absolutely black color that is certainly not desirable

But, as has been said, we realize now that shingling is not appropriate with every style of house, and is usually best on those of relatively modest size and aspect. There are many cases when painted clapboards are much better.

Of course, a white house, standing by itself in a glare of sunlight, is unpleasant to look upon close at hand, and makes an inharmonious spot in the landscape when seen from a greater distance. But this is a trying situation for any house to occupy; when it must be borne with, stone or brick, of not too deep a color, is a better material than wood; and if wood must be used and staining is not desirable, then the best thing is to choose some tint which is nearly, but not quite white,—a pale yellow or a delicate, not slaty, shade of gray. But even a very large house can be white if it is surrounded by trees, for their shadow will temper its glare. Indeed, a white house thus shadowed makes, we think, as a rule, a more beautiful effect in our landscapes than any other. There were recently exhibited in this city a number of pictures by Mr. Leonard Ochtman, painted in Connecticut, and representing pastoral scenes. In many of them the main feature was a white house, or group of houses, accompanied by umbrageous Elms. The artist had not in any degree toned down the color-scheme of New England summer nature, or tried to mitigate the whiteness of his buildings; yet the effect of his canvases was eminently harmonious, and one felt that the color-scheme would have lacked a most desirable note had the houses been anything but a true white. The pictures of many other artists have, in recent years, shown us similar things, and we can discover them for ourselves if we know how to use our eyes when we are actually looking at American landscapes. Notice, for instance, if you ascend the Hudson River, which of the houses on the hill-sides look best, and you will decide that it is almost always the white ones. None looks better than the old Catskill Mountain House, perched up on its steep bluff with a line of forest behind it. Compare its effect with that of the dull-colored Kaaterskill House not far away, and you will be glad that its original color has not been changed.

Indeed, there may be cases where a house can stand apart from trees and yet look well if painted white. This, I think, is when it stands on the edge of the sea, with strong blue color below it, and probably stretches of brilliant white beach to support its own whiteness. Certainly we should not want the color of our whitewashed lighthouses changed. It is this color, quite as much as their conspicuous simple forms, which makes them such welcome additions in any sea-shore view. A further proof of the appropriateness of white in our climate is the beautiful effect that sails make when seen against the shore. We have been foolish enough to imitate the architectural coloring of Holland under our very different skies; but at least we have never felt that our fishing-craft, yachts and sail-boats would fit better into the landscape if their sails were stained with those brownish and deep yellowish tones which harmonize so well with Dutch shores and skies and waters.

Of course, to cover a house with painted clapboards is not the only way of having it white. We might well make a more frequent use than we do of plaster and stucco in their various forms, and a half-timbered house with stuccoed panels of white would often look admirably where one all of white would be too glaring. And then there are limestones and marbles among more costly materials.

Even if absolute white is not chosen, and naturally I do not recommend that it should be used to the exclusion of all other colors, care should be taken to get a tone that is neither too deep nor too strong. Very pale yellow is often the best possible color, while, in the same situation, a deeper yellow would look crude, a neutral tint would be ineffective, a harsh brown or gray would conflict with Nature's scale of color, and a deep red roof would only make matters worse. Gray, if it is light and pure enough, is a very good color, too, especially when relieved by white trimmings and very dark green blinds, and is, indeed, perhaps the best color for houses which stand in exposed situations. It may be so chosen as to give practically the same effect that the weathering of shingles produces under the best climatic conditions.

Brick, in very pale yellow tones, is an excellent material for country houses; and, of course, any color that can be applied to wood can be given to bricks as well, and many of them are better than the strong red which once seemed their only natural hue. Very successful in color is a large old brick mansion in the neighborhood of Boston which for generations has been painted a clear and distinctly lavender gray, the painter never being allowed to mix the tint without one of the family standing by to see that he does not get it too dull and impure.

New York.

M. G. Van Rensselaer.

New or Little-known Plants.

New Orchids.

CYPRIPEDIUM × "MONSIEUR FINET," Hort.—A very distinct hybrid raised between *C. callosum superbum* and *C. Godefroyæ* by Monsieur Regnier. It is said to be one of the most beautiful hybrids known, and to be comparable with *C. × tessellatum porphyreum* and *C. × Van Houttei*. The flower is lined and spotted with green and rosy purple on a paler ground, which becomes white toward the margin of the dorsal sepal. It is quite intermediate in shape.—*Orchidophile*, 1891, pp. 321, 333, 335, with figures.

CYPRIPEDIUM × BOSSCHERIANUM, Hort.—A hybrid raised by Monsieur Ch. Vuylsteke, of Loochristy, Ghent, Belgium, between *C. Spicerianum* and *C. barbatum superbum*. The dorsal sepal is very broadly rounded, strongly reflexed at the sides, bright at the base, white above, with deep purple midvein and fine light purple nerves on either side, with paler transverse reticulations. The petals and staminode are much like those of *C. Spicerianum*, except that both are rather flatter, and the lip is about intermediate in character.—*Gardeners' Chronicle*, January 2d, p. 11.

CYPRIPEDIUM × DECORUM, Hort.—A hybrid raised by Monsieur Jules Hye-Leysen, of Ghent, Belgium, between *C. × Sallieri Hyeantum* and *C. Lawrenceanum*. The dorsal sepal is deep brown, shading into dark green toward the base and into pinkish magenta near the white margin. The lip is metallic brown in front, and paler behind, and the lip garnet, flushed with mauve.—*Gardeners' Chronicle*, January 2d, p. 11.

LEPTOTES BICOLOR, Lindl., var. BREVIS, Rolfe.—A distinct variety with short broad segments, and the front lobe of the lip broadly elliptical, obtuse, and pure white instead of purple. It appeared with Messrs. B. S. Williams & Son, of Upper Holloway, in a batch of the ordinary form.—*Gardeners' Chronicle*, January 9th, p. 42.

CYPRIPEDIUM × COWLEYANUM, O'Brien.—A handsome hybrid raised by Mr. Cowley, in the collection of F. G. Tautz, Esq., of Ealing, by crossing *C. Curtisii* with the pollen of *C. niveum*. It is fairly intermediate in character, and bears some resemblance to *C. × Marshallianum*. The flower is white, the dorsal sepal with about fifteen clear dark purplish crimson, somewhat dotted, lines, and tinged with rosy purple between them, and the petals covered with small dark purplish crimson spots. The lip is bright rosy purple, and the staminode dark purple, with a white margin.—*Gardeners' Chronicle*, January 16th, p. 73.

CYPRIPEDIUM × ENSIGN, O'Brien.—A hybrid raised in the collection of C. Winn, Esq., of Birmingham, between *C. × Harrisianum* and *C. barbatum Crossi*. Thus it is *C. × Harrisianum* crossed back with one of its parent species. It is said to resemble the first-named, but with a more shiny surface, and a more rosy hue over the petals and dorsal sepal.—*Gardeners' Chronicle*, January 16th, p. 73.

PHALÆNOPSIS SCHILLERIANA, Rchb. f., var. PURPUREA, O'Brien.—A bright rosy purple variety, with flowers darker than usual. It appeared with Messrs. Hugh Low & Co., of Clapton.—*Gardeners' Chronicle*, January 23d, p. 105.

EPIDENDRUM GODSEFFIANUM, Rolfe.—A species belonging to the *Encyclium* section, imported with *Cattleya labiata* from northern Brazil by Messrs. F. Sander & Co., of St. Albans. The sepals and petals are light green, somewhat nerved with light brown, and the lip white, the front lobe being lined with bright rose-purple, and the side lobes similarly marked at their base. The apex of the column is orange-yellow.—*Gardeners' Chronicle*, January 30th, p. 136.

CYPRIPEDIUM × GIGAS, O'Brien.—A hybrid raised in the collection of C. Ingram, Esq., of Godalming, by Mr. Bond, from *C. Lawrenceanum* crossed with the pollen of *C. Harrisianum nigrum*. It is intermediate in character, though somewhat approaching the seed parent in its flat, circular upper sepal, which is very dark chocolate at the base, lined with the same on an emerald-green ground above, and

with a broad pure white margin. The petals and lip approach those of the pollen parent in character, but the staminode is more reniform in shape.—*Gardeners' Chronicle*, January 30th, p. 136.

CYPRIPEDIUM × SWINBURNI, O'Brien.—A hybrid raised by Messrs. Heath & Son, of Cheltenham, between *C. insigne Maulei* and *C. Argus Moensii*. The dorsal sepal is green at the base, with lines of distinct brownish purple spots which decrease in size toward the broad white apical margin. The petals are greenish white, tinged with white on the outer halves, and with a number of dark purplish blotches, as in *C. Argus*. The lip is green, tinged and netted with reddish brown, and the staminode yellow with a green veining in the centre.—*Gardeners' Chronicle*, January 30th, p. 136.

Kew.

Foreign Correspondence.

London Letter.

FRUIT FROM SOUTH AFRICA.—A further consignment of fruit from South Africa arrived at Southampton on the 6th instant, and was disposed of by auction sale at Covent Garden Market. The condition of the fruit was so good that really fancy prices, even for London, were realized. For instance, boxes containing from thirty to thirty-five apples fetched seven shillings and sixpence (nearly two dollars) each, while pears in some instances sold even better, one case containing forty-two fruits realizing thirty-four shillings. Melons brought about three shillings and sixpence per box, and grapes fifteen shillings per box of twenty pounds. These prices, especially those of apples and pears, are probably much higher than the present condition of the fruit market would warrant, bar favor. At the same time, there can be no doubt that good fruit of this kind will find a ready market in England any time between February and June. That this is the case is shown by the rapid development of the trade in Tasmanian fruit, which, according to the following extract from a daily paper, will shortly arrive in England in large quantities: "The P. & O. Steamship Company have arranged that their steamers shall make twelve visits to Hobart, Tasmania, for the purpose of bringing to England a consignment of 240,000 bushels of apples. The first lot has been dispatched, and will arrive in London toward the end of the present month. The fruit is packed in cool chambers during the voyage." At this rate there is some hope that we shall soon be able to purchase such delicious tropical fruits even as the durian and the mangosteen in Covent Garden Market as fresh and as palatable as they are when newly gathered from the tree.

PLANTS FOR HOUSE DECORATION.—This was the subject of a short paper by Mr. John Wills, which was read at the last meeting of the Royal Horticultural Society. Mr. Wills has for many years held a first position among the horticultural "decorators" of England. He stated that the grand displays now produced at balls, festivals, etc., by means of plants and flowers were scarcely known twenty years ago. About that time Sir E. Scott gave *carte blanche* to Mr. Wills, whose work occupied three days. The Marquis of Bristol soon afterward had an elaborate arrangement in which no less than six tons of Ivy alone were used. Lady Sutton spent £1,000 in one month in decorative work with plants, and on one occasion a Belgravian magnate spent £1,400 on a single effort! All good for trade, no doubt, and that is the best that can be said of displays of this kind. Some of the statistics given by Mr. Wills are interesting. He found on inquiry that there are at least 300 nurserymen and market-gardeners in England who grow for Covent Garden alone; also that 20,000 van-loads of decorative plants were sent to Covent Garden last year. The plants which Mr. Wills has found most serviceable for the decorator are *Livistona Sinensis* (*Latania Borbonica*), *L. australis*, *Phoenix rupicola*, *Rhapis*, *Kentias*, and *Cocos Weddelliana* among Palms. He also recommended As-

paragus plumosus, Dracænas, Aspidistra, Hydrangea, Ferns, Crotons, Pandanus, Cycads, etc. It would take an enormous number of such plants to justify a charge of £1,400. Mr. Wills, however, in his special efforts uses such plants as Nephentes, Orchids and all kinds of flowering plants. I have seen some of these costly arrangements made by Mr. Wills, and they were certainly very beautiful. At the same time one cannot help thinking with Dr. Masters that the art sometimes displayed in the cottager's window is at any rate as pleasing.

FLOWER DYEING.—A few weeks ago a green Carnation made its appearance in the button-holes of the members of a political party in Paris, which consequently became known as the party of the Green Carnation. The badge of the Boulangists was the red Carnation, while the anti-Boulangists wore the same flower, but with its stalk uppermost. The green Carnation attracted some attention on account of its exceptional color, an English daily paper stating that this "new color in Carnations had been raised by a Parisian florist, who was in the way of making a fortune out of it!" The color was really the result of placing the flowers in a dye which soon permeated the petals and gave them an artificial color. In the *Gardeners' Chronicle* this week is an interesting account of some experiments of this kind which were made by Mr. W. Dornington and Mr. Brockbank. They procured some aniline dyes, which were dissolved in water to about the transparency of claret. In these solutions flowers of various kinds were placed, or rather their stalks, for the dyes did not change the colors of the flowers when simply immersed in them. Lily-of-the-valley became beautifully tinged with pink or blue in six hours; Narcissi changed from pure white to deep scarlet in twelve hours, and yellow became striped with scarlet in the same time. Flowers of Lapageria, Cœlogyne, Calla, Cyclamen, Snow-drop, Hyacinths, Hellebores, Tulips and other plants were treated, and gave equally striking results. White Tulips were changed to pink, blue, green or purple in a few hours, and White Lilac became pink or blue. The blue Rose, blue Chrysanthemum and red Daffodil can therefore now be made to order!

BORDEAUX MIXTURE.—A report upon the experiments made for the prevention and cure of the Potato disease (*Peronospora*) has just been published by Messrs. R. Veitch & Son, Exeter. They experimented on ten varieties of Potato, applying the mixture twice, once in June and again in July, the result being an "unqualified success, for it acted as a preventive where the disease had not appeared, and as a cure where it had done so, at the same time showing itself to have had a fertilizing effect as well." Messrs. Veitch state that the use of the mixture for potatoes last year was "a great success in many parts of America, and almost universally so throughout France, where the idea was first carried into practice." A committee of the Royal Agricultural Society of England have recommended that renewed experiments on Potatoes with this mixture be taken in hand again during the forthcoming season, and Mr. Carruthers, F. R. S., of the British Museum, has undertaken to conduct an inquiry into the exact nature of the effect of the mixture upon the *Peronospora*. Messrs. Veitch urge cultivators generally to give this Bordeaux mixture an extended and impartial trial. The results obtained by Messrs. Sutton & Sons, which I mentioned in a previous letter, were almost the opposite of those obtained by Messrs. Veitch. Evidently, therefore, the time for a verdict as to the value of the mixture in England, at any rate, has not yet arrived.

RHODODENDRON SEABRIFOLIUM.—I forget if I have mentioned this new Chinese Rhododendron, which flowered at Kew for the first time last year, when it was figured in the *Botanical Magazine* (t. 7159), where it is described as an erect unbranched plant, with scabrid, hairy ovate-acuminate leaves two and a half inches long, and a compact head of white flowers one and a half inches across. Neither this description nor the picture which accompanied it does full justice to the plant as it is now at Kew. It has six

branches, each bearing a terminal cluster of exceedingly pretty white flowers, slightly flushed with rose, and with pink anthers. The "legginess" of the plant last year was owing to its not having been stopped. With a little management it may be made bushy enough, and as it flowers freely early in the year it will be useful. So far, it has only been tried in a greenhouse, but it may prove to be quite hardy in England, for, according to Delavay, who discovered it in Yun-nan, it grows at a higher altitude there than *R. decorum*, a species very like *R. Catawbiense*, and which we also owe to Delavay. Now, *R. decorum* has stood the severe weather of the present winter in the open as well as the hardiest of Rhododendrons. We have in cultivation at Kew, beside the two species mentioned, *R. Delavayi*, said to be one of the handsomest, *R. lacteum* and *R. racemosum*. These are all from Yun-nan.

AZALEA CALYCIFLORA.—This is one of the forms of *A. indica*, and nearest that generally known as *A. amœna*, of which we possess now several pretty seedling varieties, which were raised by an English amateur, Mr. Caldwell. *A. calyciflora* differs from these, however, in having larger flowers and their color, which is a soft salmon-red. The habit of the plant is like that of *A. amœna*; like it, too, it forces well. By the way, has the last-named Azalea ever been tried out-of-doors in your country? Here it is quite hardy, forming a beautiful little shrub which is pretty at all times, and emphatically so when clothed with its rosy purple flowers. Another of the same type, known in gardens as *A. obtusa*, is equally hardy.

London.

W. Watson.

[*Azalea amœna* is well known in this country, and perfectly hardy in the latitude of New York.—Ed.]

Cultural Department.

Flower Garden Notes.

IT is in season to note a few of the desirable plants for the summer garden, both annual and perennial. We have many plants that are perennial if wintered over where the space can be spared for them. One of these is the beautiful Grass, *Pennisetum longistylum*. Last summer, when planted the length of a wide border in front of greenhouses, it was very attractive, and it will be better known in future, though it is by no means new. *Pennisetum* grows about two feet high, and can easily be raised from seed of good quality, but it can also be easily propagated by dividing the roots and starting them in small pots in spring. Our plants are now stored in a cellar with other tender plants and must now be divided and started into growth to produce good effect early in summer. The same is true of the Cannas, called dwarf, the more recent varieties of which are distinctly in advance of all others. The Star of 1891 is now a fine sight in full flower in the greenhouse here. We have eighty plants from one obtained last spring, it propagates so readily by division. A bed of this Canna alone, seen last summer, was very attractive and worthy of reproduction by those who have the plants at their disposal. When planted out, the Canna Star of 1891 grows to a height of about five feet, but under pot-culture it becomes a handsome plant, rarely more than three feet high.

The newer strains of Dahlias are to be recommended, especially the dwarf ones, both single and double. The staking, which is usually necessary with other kinds, is not needed for these plants, as they make a handsome bed of themselves. In this locality Dahlias are a complete failure after the Chrysanthemum fly appears. These insects sting the growing tips of the shoots and buds and that is the end of the display for the season. I have noticed in cottage gardens by roadsides, where the Dahlias can hardly be recognized for the dust that covers them, that they flower freely and the insects do not trouble them.

The Marguerite Carnations are rapidly gaining in favor, and have already passed through the "novelty" stage or crisis, which means usually fifty per cent. single flowers if double ones are promised. These carnations, now offered in separate colors, are fragrant and free-blooming, but to get the most out of them they should be sown at once in heat, if this has not already been done, to be pricked off singly and transferred later to the place where they are to flower. They will need

careful staking to prevent them from becoming storm-beaten when in bloom. Of China Asters tried last summer, Queen of the Market proved the best of all for cutting purposes, and was also the earliest to flower. The stems were stiff and of good length. Peach-blossom is a pretty shade of

pleasing color and as fragrant or more so than any other kind. Mignonette requires a moist soil or plenty of water applied to keep it going all the summer, and then the more they are cut the better the plants will flower, and the same is true of Sweet Peas. There is a threatened scarcity of the supply of Sweet

Fig. 23.—The Great Madroña of San Rafael—See page 146.

pink, and when grown in quantity produced a very pleasing effect, as did also the dark crimson General Jacqueminot, quite the best dark Aster I have met. With Mignonette, the Giant Crimson has proved the best and most vigorous variety indoors and outside in summer. The spikes are large, of a

Pea-seeds, and the price has been raised accordingly by some dealers. These should be among the first seeds sown out-of-doors, so that it is wise to obtain them early. If the flowers are picked clean every day they will continue to appear until frost comes. When once allowed to seed, then flowering is over.

For forwarding the numerous tender annual seeds nothing is better than a gentle hot-bed. When the fermenting material used is four to five feet thick and covered with about six inches of soil, the pots and pans may be plunged in it and receive a gentle warmth that will greatly help germination, and afterward serve as a place for forwarding the young seedlings when pricked out until time for planting out. Those who have only a cold frame in winter should excavate within it to the required depth, and fill this in the spring with fermenting material that has been mixed with leaves a day or two and allowed to become warm. It can then be trodden firm in the frame and used at once for sowing seeds if six inches of soil has been placed on top. This is the best place for sowing seeds of Asters, Stocks, Zinnias, Tomatoes, Peppers, Egg-plants and many more of a like character. The frame may be used in summer for Cucumbers or Melons in places where these do not thrive in the open, as, for example, in this section.

E. O. Orpet.

The Cultivation of Bulbs in the South.

IN the January number of the *American Agriculturist* Mr. Thorpe called attention to the fact that the production of tuberous bulbs and plants for the American and European markets has become centred in one or two localities in eastern North Carolina. He also speaks of the great adaptability of the warm coast plain of North Carolina to the production of bulbs that are now imported by the million from foreign lands, just as the Tuberose was brought from Italy thirty years ago. There is a wonderful future for this favored section in the hands of skillful cultivators. Of Narcissus alone varieties by the hundred and bulbs by the million are imported annually from the south of Europe, all of which could be grown to better advantage in eastern North Carolina at much lower prices than they now cost, and it will be just as easy for growers here to monopolize this culture as they have that of the Tuberose. Many of these Narcissus are too tender for the open air in the northern states, but all can be grown here to sell to the northern florists for forcing purposes. The gorgeous family of Lilies, too, would find here a congenial home. *Lilium longiflorum* is diseased in the north, while here it grows in perfect health. In the black peaty soils of eastern North Carolina the Bermuda Lily, I feel sure, can be grown to a greater perfection of bulb than in the thin soils of Bermuda. Our native *Amaryllis*, which grows so profusely in a wild state, can also be profitably cultivated for the northern wholesale trade. All the gorgeous tribe of *Amaryllis*, which are nursed in pots at the north, can be grown here in the open air, and many of them sell now at prices which would make their culture profitable to the intelligent grower. Roman Hyacinths in this peaty soil develop bulbs of great size and vigor, and they continue to bloom profusely much longer than at the north. The plants begin to bloom here about the 20th of December, and throw up spikes of flowers without intermission till late in March, a season of bloom unsurpassed elsewhere. Here, too, the popular Tuberous Begonias find a long season for perfect development, and their tubers rest unharmed in the ground all winter. *Gladiolus* will ripen two crops on the same land in one season, and make corms of enormous size. *Sternbergia lutea*, the yellow fall-blooming *Amaryllid*, develops a magnificent growth in our mild winters (their season of growth). *Cannas* keep perfectly in the ground where they grow, and can be dug for shipment all through the dormant season. *Caladiums* of all kinds make superb tubers, from the chopped up rhizomes, in our long seasons.

In fact, then, in the whole list of bulbs and tubers now used so extensively, and imported from abroad, there are none that cannot be better grown in the coast region of North Carolina, where the soil is that of Holland and the climate that of Italy.

Raleigh, N. C.

W. F. Massey.

Early Irises.

IRIS HISTRIOIDES is one of the latest additions to the list of early-flowering bulbous Irises. It is a native of Palestine, and has been introduced to cultivation by Herr Max Leichtlin. We are again indebted to the great Baden-Baden gardener for a first-rate plant for the early garden. *I. histrioides* is one of the reticulata group of Irises, and follows *I. Bakeriana* closely in time of flowering, coming into bloom in my garden early in March this season. In this latitude the weather in early March is a very variable quantity, and it is somewhat difficult to describe the habit of plants with experience gained only from those fully exposed to the vagaries of the climate. The first flower from this variety, probably from being caught by very

severe weather, was only one inch high, but later blooms are expanded at three inches, which is rather taller than *I. Bakeriana*. The flowers vary somewhat in color, but are shades of purple, with golden keels and purple markings on a white ground. One especially beautiful one was spotted with deep royal purple markings. There are also said to be white forms of this variety. The flowers are delicately fragrant and thoroughly weather-proof. Frost of fifteen or twenty degrees they heed not at all, high winds they do not nod to, and warmth sufficient to melt snow starts them into activity. The last flower expanded promptly as the last of six inches of snow which had covered them disappeared. It seems to me that this is a charming and valuable plant.

A clump of *I. reticulata* will not be in full flower till early in April. These, while a little later, are among the most charming of early flowers, and are not as commonly grown as they should be. The typical *I. reticulata* is entirely satisfactory, admirable in color, fragrant and hardy. Numerous forms of this have been raised from seeds, one of the most striking being *I. reticulata major*, somewhat larger than the type, with a very beautiful flower of deep honest purple, with golden markings. This is an English variety, and the best form yet seen by me. The form which I know as *I. reticulata Krelagei* has a reddish cast, and does not appeal pleasantly to my color-sense. *I. reticulata* seems to be a favorite plant with Herr Leichtlin, and he has raised a number of new forms, some of which are said to be very handsome and satisfactory blues, but these have not been grown in my garden.

I. Danfordiae is a yellow-flowered Iris of the same group, which seems somewhat more shy in blooming. At least the bulbs in my border are again not inclined to flower. Perhaps their location is too wet and cold, for these Irises seem happier in a sunny and rather dry border, sheltered from north winds.

We are promised a wider range of color in *Iris Bakeriana*, reaching from the blue of the type to white. Probably the varieties will be no handsomer than the charming one first introduced, the falls of which are so beautifully marked with a rich velvet-blue on ground of white and light blue. This Iris on second trial proves entirely hardy even in wet soil, and increases rather rapidly by offsets. If seed were desired it would be necessary to grow it under shelter, as it flowers so early in the year that no seeds are set in the open. The flowers are very lasting, and, though opening in late February, they are not affected by the hard weather of that season. Usually they retain their form for a fortnight.

Notes on Begonias.

BEGONIA BISMARCKI.—This comparatively rare and beautiful garden hybrid is one of the best winter-blooming varieties we have. Its constitution is very robust, and partakes generally of *B. rubra* in character. The leaves, however, are larger, and much more divided. The panicles are large, and so, too, are the individual flowers, which often measure two or more inches across. The male flowers, which, as in all Begonias, open first, are comparatively small, and it is not until the female flowers display themselves that their full beauty is seen, the large seed-vessel, with largely developed, bright red wings, being their most conspicuous feature. The petals are light rose, incurving slightly—a form which adds considerably to their effect. The plant is easily propagated, the cuttings bloom in the propagating-bed and grow into neat plants at once. For bedding it has exceptional merit, since very few of its class bloom well during summer. As a cut-flower variety it is excellent, the flowers lasting a long time.

Of the many fine varieties raised from *B. semperflorens* the large red one, with its unwieldy catalogue name of *Begonia sempervirens robusta gigantea rosea*, is the best. It is a good, all-around Begonia, either for bedding in summer or blooming in the greenhouse in winter. It makes a handsome specimen from the time it is rooted as a cutting, and every shoot blooms from the first growth made. The leaves are bright shining green, nearly round, and five to six inches in diameter. The stems, petioles and foot-stalks of the flowers are red, which adds somewhat to their beauty. The flower-stems are stout, erect, long enough for decorative work, bearing dense panicles of large vermilion-red flowers. I have some fine specimens, less than one year old, in eight-inch pots, which are more than three feet in diameter by two feet high.

The well-known *B. glaucophylla scandens* (Comte de Lenninge) is very generally used for basket-work; but for draping a pedestal it has a unique value. Two plants which I have in view are grown in large pans, in which they have been two years, and these set on pots, which they drape completely.

They are now covered with short dense panicles of brick-red and white flowers. The female flowers, with white seed-vesicles and large red wings, are in beautiful contrast to the red male flowers, and handsome white-margined, glaucous foliage. To have this species bloom well in winter a little rest or partial drying should be given after blooming, say, from June to August. A few cuttings taken now and rooted would make, if placed five in a pan, a neat specimen for next winter, but would not bloom so well as two-year-old plants which had been rested in summer.

B. Verschaffeltiana is a rather common, but handsome hybrid between *B. carolinæfolia* and *B. manicata*, and though it is intermediate in character, it is evidently more robust than either parent. It is tall, coarse and unsightly as an old specimen, but when well grown from year to year as a cutting, it makes a splendid plant. The leaves are palmate, about one foot in diameter, very similar in shape to those of *B. manicata*. The cymose panicles of lilac-colored flowers have a clear and graceful spread of eighteen inches or more, and are supported on stout stems two feet long. An individual panicle will remain well in bloom for two months, and as flower-stems appear in succession, both from the main stem and side shoots, the plant may be said to bloom the whole winter. Certainly it has presented an effective display of bloom for more than three months. The whole plant presents a one-sided appearance, no matter how it may be exposed to light. This, however, appears to be rather an advantage, as the plants are faced about.

Wellesley, Mass.

T. D. Hatfield.

Arachnanthe Cathcartii.

THIS remarkable and beautiful Orchid is, unfortunately, but too rarely seen in flower. Only in a few collections, apparently, does the gardener seem to possess the knack of inducing it to bloom annually. Recently, at one of the meetings of the Royal Horticultural Society in London, a spike bearing three large flowers was exhibited by Mr. W. Iggulden, of Marston Gardens, Frome, who grows the plant successfully, and who informed me that previous spikes produced by the plant had borne four flowers. Individually these are about three inches in diameter, with roundish oblong sepals and petals, creamy outside, and pale yellow on the inner surface, which is transversely marked with wavy and often confluent bands of deep reddish brown, which give the segments a beautiful arachnoideous appearance, like that of some *Stapelias*, *Huerrias* and allied genera of *Asclepiadaceæ*. The lip is remarkable; the small side lobes are roundish, intumed and streaked with crimson or red. The middle lobe, however, is much larger, and reminds one very forcibly of the sole of a horse's hoof, with its ridges and depressions. The border is buff-yellow, while the centre is of a clear shining white—the whole being very fleshy and brittle, and easily movable at the slightest touch or breath. The plant itself grows several feet long, like *Renanthera coccinea*, having stems as thick as a lead-pencil. The leaves are borne chiefly on the upper portion, and are six to eight inches long, strap-like and very leathery, with an oblique two-lobed apex.

The generic name, *Arachnanthe*, established by Blume, has not yet universally commended itself to gardeners, who in the matter of names are most conservative, and in this particular instance prefer the older, shorter, but, nevertheless, erroneous name of *Vanda*, applied to the plant by Lindley when describing it in his *Folia Orchidaceæ* in 1853. The differences between *Arachnanthe* and true *Vandas* are palpable enough, and need not be entered into here. Suffice it to say that for many years the species now under consideration has been considered as not a *Vanda* at all. The late Professor Reichenbach therefore established a new genus expressly for it, and called the plant *Esmeralda Cathcartii*. Bentham, however, discovered that *Esmeralda* of Reichenbach was practically identical with the *Arachnanthe* of Blume; hence in that standard work, the *Genera Plantarum*, the name *Arachnanthe* has been retained in preference to *Esmeralda* on account of its priority.

The discovery of *Arachnanthe Clarkei* is claimed by Sir Joseph Hooker, who, in describing the plant in the *Botanical Magazine* under tab. 5845, says: "It is a native of hot, damp, shady valleys in the eastern Himalaya, delighting in the neighborhood of waterfalls where exposed to constant humidity. . . . It was discovered by myself in 1848, and transmitted to the Calcutta Botanic Gardens, where, after flowering, it was sent off to England, but did not survive the voyage." Reichenbach, however, in reference to the discovery, states in the *Xenia Orchidaceæ* that "long before the expedition of Drs. Hooker and Thomson, Dr. Lindley had received it from Griffith with

numerous flowers of other curiosities preserved in large glasses of alcohol." Although numerous attempts were made to introduce living plants, the failures to do so were many. It appears, however, that at length Messrs. Veitch were not only successful in obtaining living specimens, but were the first to flower the plant in March, 1870, and in October of the same year a plant six feet high produced several flowers in the collection of Mr. C. Stead, of Baildon, near Leeds.

At one time great difficulty was experienced in the cultivation of *A. Cathcartii* (which is named after Mr. James F. Cathcart, who was one of the earliest explorers in the eastern Himalayas), but now that its wants are better understood, it ought to be managed with tolerable ease. It may be either trained on a wall or grown in a pot filled with clean crocks, the surface of which should be covered with fresh sphagnum. In the latter case it will be necessary, owing to the rambling habit of the plant, to put a stick to it. There should always be plenty of moisture in the atmosphere, and if the upper portion of the plant is allowed to assume a more or less horizontal position there is, for some reason or other, more chance of flowers than if the shoots are trained bolt upright. The thermometer in the winter months should register from sixty to sixty-five degrees, Fahrenheit, at least during the day, with a drop of only a few degrees at night-time. In the summer months this matter will be more easily regulated, but attention should then always be given to watering and occasional syringing, so as to supply continually the moisture which must inevitably go off in evaporation, especially if air is admitted into the houses to any extent.

Isleworth, London.

John Weathers.

Chrysanthemum Blight.

IN an article on Fungus Troubles in the Cutting-beds, published in GARDEN AND FOREST February 24, 1892, page 91, Dr. Halsted calls attention to the severe blighting of *Chrysanthemum*-foliage and damping-off of *Chrysanthemum*-cuttings due to a fungus of the genus *Septoria*. A *Septoria* was also found abundant last fall on *Chrysanthemums* at the station and at greenhouses in this vicinity. Specimens of this *Septoria* submitted to Dr. Halsted for examination were found to be identical with the one referred to in the article above mentioned. During the winter some experiments have been tried for the purpose of controlling this disease, and at least one of the fungicides used promises to give good success.

Cuttings from diseased plants were struck about January 1st and potted off in due time. The blighted foliage was removed February 8th, and the plants were divided into three series. Series 1 was sprayed once a week with potassium sulphide; series 2 was sprayed once a week with ammoniacal solution of copper carbonate; series 3 was left untreated for comparison with the other two series. Without giving detailed notes of the experiments, it may be said that the potassium sulphide solution has given good results, but not so good as the ammoniacal solution of copper carbonate. Plants treated with the latter remedy show less of the disease, and are much more thrifty and vigorous than are the same varieties of series 1 and 3.

Further experiments with other fungicides are also in progress, and it is expected that the results will be published when the work is completed. Attention is here called to the beneficial effects which have thus far attended the use of the copper carbonate solution, with the hope that *Chrysanthemum*-growers may be led to make further tests of this remedy. It may be well to state that excessive or careless use of the remedy has proved injurious to the foliage of some plants. In the experiments here reported, however, no injury to the foliage is apparent. The solution is, of course, applied to all parts of the plant in a very fine spray without drenching them. The formula used is five ounces of copper carbonate dissolved in three pints of strong ammonia (twenty-six per cent.) and diluted to fifty gallons. A convenient way is to dilute the mixture to six quarts, and keep this strong solution on hand in tightly corked bottles. When the dilute solution is needed for use it may be easily prepared by adding a gallon of water to one pint of the strong solution.

Geneva, N. Y.

S. A. Beach.

Manettia bicolor.—This pretty winter-blooming greenhouse climber, although very common, is rarely well grown. The best success is secured when young plants are grown all summer without blooming. Old plants, when cut back, never break well at the bottom and always look ragged. I have usually grown my specimens in pyramidal form, by taking long, pliant stakes and tying them in at the top, but it always appeared to me that the plant, unable to reach its limit of growth, became top-heavy. This winter I placed one near

a large circular iron support, of which it has taken advantage, and is now well on toward the roof, blooming every inch of the way. Next season I hope to have two or three plants at the base of this support and expect to see them mount clear to the roof. The *Manettia* can be increased from seeds, which ripen freely, or from cuttings.

Acacia Drummondii.—No *Acacia* can be so easily propagated from cuttings as this one, a very pretty and distinct species from Swan River. This, taken with the fact that it makes a very neat specimen and blooms while small, should make it a close competitor for popular favor with the more common *Cytisus racemosus*. The leaves, with a very short petiole, bear twin pinnæ, with very few obtuse glaucous leaflets. The drooping cylindrical spikes of yellow flowers look very much like the male catkins of a Willow. This, as well as other *Acacias*, should not be planted in the open soil unless the plants have a well-developed ball of roots. Until that time they should be plunged in pots, where an abundant supply of water at all times can be given. Peaty soil is generally recommended as most suitable, but I find these plants are not at all fastidious in this respect. Any good loam will do, free from fresh manure.

Wellesley, Mass.

Correspondence.

Grafting.—I.

To the Editor of GARDEN AND FOREST:

Sir,—The interesting paper of Professor Bailey on grafting suggests some experiences corroborative of his judgment that grafting is not a devitalizing process.

When I bought the farm which I have had since 1871, its former owner showed me a small Pear-tree which he had planted six years before, and which had made no apparent growth. I pruned, fertilized and watched it for several years. In the spring it opened its leaves, it shed them in autumn, but it made no visible growth of wood. I then removed it to a seemingly better position, to see if change might awaken it. Digging it up carefully I could not see either in roots or top any indication that they had increased in size a particle since taken from the nursery. It was a case of complete vital inertia. For nearly ten years longer it stood unchanged. It merely lived, and bore an annual crop of leaves without growth. Some years ago, while top-grafting other trees with the Kieffer Pear, I cut off all the branches of this dormant tree and inserted in their stumps cions of the Kieffer. These were set in April. Every one of them grew, and the next October many of them were over five feet in length. From the date of this grafting this inert Pear-tree has grown vigorously, its trunk has trebled in diameter, its branches spread luxuriantly, and in 1891 it bore a bushel of fine fruit.

In a Pear-orchard, which I planted in 1872, stood a Bartlett tree some five feet high with a small branched top. Yearly it blossomed, but did not grow. I pulled off the blossoms annually to direct its energies to the development of wood, but it failed to do more than blossom and bear a few leaves. To encourage it I let it bear two or three pears; these were fine fruits. But even this indulgence did not improve its disposition; it would not grow. In April, 1886, when top-grafting, a neighbor came to learn the art. I had finished my work, but my obstinate little Pear-tree stood handy, so I sawed it off to give my friend a lesson in grafting. He stuck into it a couple of Kieffer cions, and under my instructions completed the job. Those grafts grew strongly; in a couple of years I cut away one of them, and the other is now ten feet high, and was last year so burdened with fruit as to be in danger of breaking down.

I could give many other illustrations in Apple and Pear trees of the evident vitilization of the stock by the graft. The Kieffer Pear especially seems as if its vitality will revitalize any Pear-stock on which it may be worked. It shows strong growth on all Pear-stocks, but stronger on some varieties than on others, proving that there is a difference in congeniality of temperament. I have top-grafted the Kieffer on the Bartlett, Clapp, Sheldon, Anjou, Lawrence and many others. On the Sheldon and on the Mount Vernon the union of the cion with the stock is so intimate and complete that it needs close inspection to perceive where the junction is made. In 1891 the top-grafts on all these trees were so loaded with fruit that many of them broke down; but in no instance did this breakage occur at the point of union. Such has been the case in my Apple-orchard, where nearly every tree was top-grafted after ten years of growth. Here many limbs are broken by last summer's crop,

but there are no breaks at the junction of stock and cion. This, like a splice, seems to be the strongest part.

In these top-graftings it has been of interest to note the influence of the stock upon the graft. The Kieffer Pear has characteristics so marked as to be always recognizable, but these are in some degree modified by the habit of growth of the variety on which it is worked. The Kieffer graft grows differently on a Sheldon or a Clapp from what it does on Lawrence or Anjou. It also varies in the quality of the fruit. With me it is much better on the Seckel and on the Sheldon than on any other stocks I have grafted. I once took some well-ripened Kieffer pears, grown on Seckel stocks, to Mount Holly Fair, and submitted them to the taste of leading horticulturists and fruit experts. They pronounced these Kieffers "among the best pears they had ever tasted."

Among horticulturists it is a matter of dispute as to whether the stock influences the graft. I know of no systematic experiments to decide this question, but I have made many observations. I have been grafting and budding trees and shrubs for fifty years, doing much of this work simply for experiment, and my observations satisfy me that the nature of the stock does influence the nature of the graft. I have trees in my orchard top-grafted with cions taken from one tree—a Red Astrachan—on a neighboring farm. When these grafts on my trees bore fruit scarcely any one would believe the apple to be the same as those on the tree from which the grafts were taken. And these same Astrachan grafts on trees of different sorts differ from each other in habit of setting of the fruit and in time of ripening. I have the early Lippincott grafted on trees which were previously Fallawater and Spy. There is a marked difference in size and quality of the Lippincott fruit on these two sorts. I brought grafts from a tree of the Kentucky Jennetting growing on my old farm in Illinois, and with them here top-grafted a Fallawater-tree. The Jennetting here retains its habit of not opening its buds until after all other sorts in the orchard have blossomed; but I can see no similarity in its fruit here to the fruit which the Illinois tree used to bear. The apples look somewhat alike externally, but there is no other resemblance. In grafting the Grape I have seen a marked change produced in the Ives by grafting it on the Concord. It is larger in cluster and berry, and about five days earlier in ripening.

Vineland, N. J.

A. W. Pearson.

Myosotis palustris.

To the Editor of GARDEN AND FOREST:

Sir,—Near this place the railroad track passes through a piece of moist meadow-land in which a brook takes its rise, and all spring and summer this meadow, as well as the bottom of the brook and its sloping banks down to where it flows into Lake Michigan, are a sheet of beautiful blue, the color coming from an abundant growth of the common European Forget-me-not, which has been naturalized here. Whoever has seen a German meadow, the long grass flecked in a close pattern with the lovely blue *Vergissmeinnicht* and waving in the wind, blending the colors in most pleasing manner, or he who has seen this Wisconsin meadow illumined by spring sunshine will carry in his mind a picture never to be effaced. These plants were naturalized more than a generation ago by an intelligent German, Charles Kuehn.

Nothing is easier than to establish the Forget-me-not. If it is only set where the seed can reach a flowing stream, in a short time it will have spread wherever the water runs. The only danger to guard against will be the uprooting of the original plants, and it will be well to start them where some friendly hand can protect them.

Two Rivers, Wis.

Chas. L. Mann.

Baccharis halimifolia in Atlantic County, New Jersey.

To the Editor of GARDEN AND FOREST:

Sir,—The size to which *Baccharis halimifolia* grows in Atlantic County, New Jersey, is, I think, worthy of notice. Along the borders of the salt-marshes near Atlantic City I have often found it measuring from three and a half to four inches in diameter three or four feet from the ground, and from ten to twelve feet high. It certainly merits the name Groundsel-tree, as it assumes a tree-like form at least in this locality. Its conspicuous beauty in the fall of the year proves that it is worthy of cultivation, as has been already noted in GARDEN AND FOREST (vol. iv., p. 468). As bearing upon the possibility of its successful culture away from salt-water, I may state that I have found it as far as fifteen miles inland, and in places where

there never could have been any brackish water. I may add, however, that it was always found growing along streams or near wet places.

Pleasantville, N. J.

John E. Peters.

Exhibitions.

The Boston Flower Show.

THE annual spring flower show of the Massachusetts Horticultural Society filled its larger hall last week with a collection of flowering plants which, in some respects, was the best seen in recent years at one of these exhibitions, although the low temperature of the opening day made it impossible to bring large specimen plants to the city.

Nothing from the cultural point of view equaled a collection of Persian Cyclamens staged by Mr. Kenneth Finlayson, gardener of Dr. C. G. Weld, of Brookline. The plants were marvels of good cultivation, clean and healthy, with large foliage and quantities of large well-colored flowers. As specimen plants nothing so good has been seen in Boston before. From the same establishment were sent a collection of Cinerarias, which are there made a specialty, although this year the plants were hardly equal in finish to those which Dr. Weld exhibited last year. His bulbs, too, especially Hyacinths, were very fine, as were those exhibited by John L. Gardner and N. T. Kidder. Hard-wooded greenhouse-plants never appear at Boston flower shows in any great variety, unfortunately, for certainly there was nothing more interesting in this show than the Chorozemas, Eriostemons, Boronias and Grevilleas exhibited by Mr. Gardner.

Siebrecht & Wadley, of New Rochelle, exhibited ten varieties of Pitcher-plants, including a new seedling, which received a certificate of merit. Tea Roses were shown in good condition, although none of the collections were exceptionally fine. It is a suggestive fact that Tea, and not hybrid Perpetual Roses, were chiefly exhibited this year in Boston. It is to be hoped that this is an indication that the extravagant habit of forcing hybrid Roses is going out of fashion, and that the more beautiful and delicate Tea Roses are again to take the first place in winter decoration.

The display of Carnations, owing to the great encouragement in the way of prizes given this year to these flowers, was superior to any previous one, the principal contributors being R. L. Lombard and William Nicholson.

Orchids did not make a feature of the exhibition, although small well-grown collections were staged by E. W. Gilmore, of North Easton, John L. Gardner and N. T. Kidder, Mr. E. Butler setting up a remarkably well-grown plant of *Dendrobium nobile*, which took the first prize for a single specimen. The first Theodore Lyman prize for ten Orchids was awarded E. W. Gilmore, and the second to John L. Gardner, Mr. Kidder taking the first of the society's prizes for three Orchids, and Benjamin Gray the second. For stove and greenhouse plants Dr. Weld took the first, and Mr. Gardner the second prize. The first two prizes for six Cinerarias, the first and second for three plants, and the first and second for a single plant went to Dr. Weld, who also captured the first prizes for Cyclamens and Hyacinths and for the best three pots of *Lilium Harrisii*. To Warren Elwell was given the first prize for a general display of spring-flowering bulbs, open to florists only, and to R. L. Lombard the first prize for six varieties of Carnations, the second going to William Nicholson, and the third to H. K. Southworth. Paul Richwagen was awarded the first prize for twelve blooms of any crimson variety of Carnations with Ferdinand Mangold, and Galvin Brothers for twelve blooms of any pink variety with The Princess. The same firm took the first prizes for any scarlet variety with Hector, and for any white variety with Mrs. Fisher, while Golden Triumph, shown by R. L. Lombard, was considered the best yellow, and Waban, the best Tea Rose introduced since 1889.

Periodical Literature.

A good idea of the character and composition of the forests which cover the southern Alleghany Mountains, the richest and most productive forests of deciduous trees in the world, is obtained from a report made by Mr. Jed. Hotchkiss, of Staunton, Virginia, on an investigation of the standing timber of the Guiandot Coal-land Association situated in Wayne, Logan and Lincoln counties, in the south-west corner of West Virginia, and published in a late number of *Science*. The principal timber-trees on about nine thousand acres were counted and measured, and in this way some reliable infor-

mation has been obtained of the present average condition of the forests of this region. The diameter of the trees was taken at about four feet above the ground, and the length of trunks fit to cut into logs or for long timber was estimated by an expert timber-viewer. Trees less than eighteen inches in diameter, with the exception of Hickories and Locusts, which were measured from ten inches upward, were not included in the estimate. To show graphically the results of these measurements, Mr. Hotchkiss selects "a tract of 655 acres on the top of the dividing ridge between the waters of the east and the west forks of Twelve-pole River, two miles north-east of the new mining town of Dunlow, on the Ohio extension of the Norfolk and Western Railroad and about forty miles south-east from the Ohio River." About one-half of the tract lies on the east side of the dividing ridge facing to the north of east, and the other on the west side sloping south of west, the crest of the hill being about one thousand feet above the level of the sea. It was found that 16,989 trees, or an average of twenty-six large timber-trees to the acre, were growing on the 655 acres. Of these 1,986 were White Oaks, 5,886 were Chestnut Oaks, 1,100 were Black Oaks, 736 were Red Oaks, 2,547 were Hickories, 1,900 were Chestnuts, 207 were Locusts, 330 were Maples, 333 Birches, 858 Liriodendrons or Tulip Poplars, 939 were Pines, and 167 were Lindens.

It will be seen that the proportionate percentage of hard woods—that is, of all the trees with the exception of the Lindens, Pines and Liriodendrons—is remarkably large, or about eighty-eight per cent. The record of the diameter and length of each of the trees counted shows that most of them are of large size, the Oaks ranging in diameter from eighteen to sixty inches, and in trunk length from twenty to sixty feet. The Hickories range from ten to twenty-seven inches in diameter, and from fifteen to sixty feet in trunk length; the Pines from eighteen to forty inches in diameter and twenty to seventy feet in trunk length, and the Tulip Poplars from twenty to sixty-six inches in diameter and from thirty to eighty feet in trunk length.

Notes.

Mr. H. E. Chitty, of Paterson, New Jersey, writes to *The American Florist* that 3,840 plants of the Carnation Lizzie McGowan, occupying a bench surface of 1,100 square feet, produced 60,550 prime flowers in 119 days, while 50,000 cuttings were taken from the plants during the last month of the time covered by this record.

The third series of Hooker's *Icones Plantarum*, consisting of ten volumes, with a thousand plates, has recently been completed. This work, in which are figured new plants from all parts of the world, is indispensable to working botanists, and as only two hundred and fifty copies are printed, this series, like the previous ones, must soon become scarce and difficult to obtain. We are glad, therefore, to be able to announce that a few copies are still to be had from the Director of the Royal Gardens at Kew, where the work is prepared with the aid of a fund left by Mr. George Bentham for the purpose. The price of the set of ten volumes is only £5, or twenty-five dollars.

Monsieur Edward André, the distinguished landscape-gardener and the editor of the *Revue Horticole*, has been elected a member of the National Society of Agriculture of France in the section of "cultures speciales" to fill the vacancy caused by the death of the late Monsieur Hardey. Membership in this society, which is connected with the Institute of France, is limited to one hundred, and is regarded the highest honor within reach of French cultivators of the soil. Monsieur André's associates in the section in which he will take his seat are Duchartre, Pasteur, Chatin and Henri de Vilmorin. It is eminently fitting that art in gardening should be represented in this august body; and no man in Europe so well deserves the honor of representing it or can speak with so much authority as Monsieur André.

Professor Halsted writes that he has observed during the past winter that eel-worms (nematodes) have been very destructive among young Ferns. The first leaves of Ferns are very small and delicate, and two or three worms are sufficient to destroy a plant, from which they pass on to the next victim. In one bed of young Ferns noticed the dead plants were separated from the living by a line as distinct as that between the burned and unburned portion of a meadow in early spring. These pests usually attack plants from the root, and probably at the outset have made their entrance into the Ferns from the soil, but they can also spread from leaf to leaf throughout all

the plants in the bed. The soil on which the Fern-spores are to be sown should be subjected to a high heat some time before that operation. This will destroy all nematodes in the soil, and after that lime-water, sulphur and other applications known to be injurious to the worms, but harmless to tender vegetation, should be used.

When flowers are placed near a wall-painting in Japan the greatest care is taken to secure harmony between the two, so that, viewed together, they may form a single agreeable decorative composition. Beside a long painting a low composition will be used, but when the picture is short and broad the flowers may stand high and full. If lake or river scenery is represented in the painting, water plants will usually be chosen for a floral arrangement, forming, as it were, the foreground to the painted landscape. The same kinds of plants, however, must never be repeated, because those in the picture would necessarily suffer by close comparison with their natural prototypes. In front of a painting which represents some flower of the season, a vase of water is often placed in which lie a few fallen blossoms and petals of the same flower, thus continuing the idea of the picture without giving rise to unfortunate comparisons. If a verse of poetry is inscribed on a wall scroll, flowers which illustrate the poem may be set beneath it, but some critics proclaim that this should never be done, as the sight of the natural flower restricts the imagination and may detract from the force of the sentiment expressed by the poetry.

The last number of the *London Garden*, which we have received, speaks of our Newtown Pippin as "an apple of the highest and finest flavor, a delicious combination of the acid and the slightly sweet which leaves no unpleasant reaction. It is an apple, too, which shows the weakness of the ordinary classification of dessert apples and cooking apples, for while it is the most perfect of apples for dessert-eating, it is also a perfect apple when stewed in its own sugar." What is of more interest, however, to American growers is that the demand for it in the London market has led some of our exporters into sending fraudulent barrels containing other kinds of apples and labeled as Newtown Pippins. The writer had seen one of these packages which bore all the external marks of containing the choicest of Newtown Pippins, but the apples, although large and fair, were absolutely devoid of the flavor of the genuine fruit. Such practices as this would soon ruin the reputation of these apples. Since we have a fruit which, when properly grown, excels in delicacy of flavor, the greatest care should be taken to prevent a substitution of any counterfeit, for this will inevitably cause a general suspicion of the stock and break down prices.

We have received a copy of the *Lakes and Summer Resorts in New Hampshire*, which has been issued by the Board of Agriculture of that state. It consists of nearly a hundred pages, with many beautiful pictures of lake and mountain scenery, and gives an authentic list of the summer hotels and boarding-houses of the state, with brief descriptions, names of proprietors, charges, etc. Two years ago efforts were first made by the state to advertise its abandoned farms and natural attractions, and it is said that four hundred and fifty of these vacant farms have since become occupied and the summer boarding business is largely increased. This pamphlet is issued to reply to the numerous letters of inquiry which are received about these subjects. The enterprise of the State Government is certainly to be recommended. Too much cannot be said of the grand mountain scenery and of the six hundred lakes which are scattered over the state. Many large estates and extensive private parks have already been established in New Hampshire, one of the latter containing 21,000 acres. These large estates are multiplying rapidly, and although we can hardly credit the statement of the pamphlet that "the time is fast approaching when New Hampshire will be one grand park," nevertheless it is true that rare opportunities are still offered for those who desire a country home, and especially a summer home.

Dr. C. B. Graves writes in the *Bulletin of the Torrey Botanical Club* for March that he has found in south-eastern Connecticut "a small but flourishing station" of *Phlox maculata*, the Wild Sweet William, which *Gray's Manual* describes as at home from "New Jersey and northern Pennsylvania to Minnesota and south to Florida and Arkansas." Dr. Graves saw the plant in a meadow beside Jordan Brook, in Waterford, about four miles from New London, and says: "So far as observed it is confined to two patches, the larger of which comprises an area of thirty or thirty-five square yards, the smaller less than half as large, lying thirty or forty rods farther down

the brook. The plant grows very thickly in both these patches, and when in bloom fairly illumines the meadow. The interest in this station lies in the question whether the plant is or is not indigenous here. Only a little way from the meadow is a farm-house which has been occupied by the same family for several generations. There is no tradition in this family as to its ever having been introduced, and no one now living remembers a time when it did not grow in its present position. Furthermore, it is not found in any garden in the neighborhood, and, in fact, I have never seen it in cultivation in this vicinity. All these facts point to its being a native. On the other hand must be mentioned its very limited distribution, its occurrence so far north and east of its recorded range, and its nearness to human habitations. If introduced it must have been at some remote time in the past."

Mr. R. A. Rolfe writes that the economy of fertilization in the Swans-neck Orchids (*Cycnoches*) is very interesting, and only from this standpoint can we hope to understand the great diversity between the sexes in the majority of the species. In both the lip is uppermost, and forms a kind of landing-stage on which insects which visit the flowers alight. In all probability it is the insect's abdomen which comes in contact with the tip of the column, as the action can easily be imitated artificially. But in the case of the male flower a very curious mechanism comes into play. The stipes of the pollinium are tightly strained around the rostellum, but as soon as the sensitive filament is touched the pollinium is liberated and ejected from the flower by its own elasticity. During its short flight it not only straightens itself, but curls up into a spiral in the reverse direction, tightly clasping the anther-case, but leaving the viscid disk exposed, and this becomes tightly glued to the body of the insect. The pollen is now wrapped up in the anther-case, but the filament is hygroscopic, and being exposed to the air it soon dries and straightens itself, when the anther-case, having served its purpose, falls away. Meantime the insect will have visited other flowers, and if one of these is a female the pollen would come in contact with the viscid stigma, between its pair of fleshy wings, and thus fertilization is effected. In the early morning these plants exhale a most powerful perfume, which serves to attract the insects. And now we may see the curious way in which the different structure of the male flower of the section *Heteranthoe* comes into play. In the section *Eucycnoches* the lip of the male is ovate, fleshy, and immovable (as in the females of the entire genus), so that it is by the movements of the insect that its body comes into contact with the apex of the column. But in the flowers of section *Heteranthoe* the lip is reduced to a small, round disk with radiating teeth, and instead of being immovable it is attached by a slender hinge, and as soon as the insect alights its weight depresses the hinge, and its body comes in contact with the apex of the column with some force, invariably liberating the pollinium. It is marvelous how perfect all these adaptations are, and it has been a work of the greatest possible interest to me to trace their action and use.

Catalogues Received.

J. B. ALEXANDER, Hartford City, Ind.; Price-list of Fruit Trees, Small Fruits, Ornamental Trees and Shrubs.—ANDORRA NURSERIES, Chestnut Hill, Philadelphia, Pa.; Hardy Trees, Choice Shrubs, Plants, Roses and Fruit.—JOSEPH BRECK & SONS, 51, 52, 53 N. Market St., Boston, Mass.; Novelties and Specialties in Vegetable and Flower Seeds, Bulbs, Roses and other Flowering Plants, Shade, Ornamental and Fruit Trees.—E. F. BROCKWAY, Ainsworth, Iowa; Price-list of Transplanted Evergreen Trees.—A. T. COOK, Hyde Park, Dutchess Co., N. Y.; Vegetable and Flower Seeds.—JOHN W. DOUGLASS, 57 Beekman Street, New York, N. Y.; Illustrated Catalogue of Implements for the Farm.—GRAHAM, EMLEN & PASSMORE, 631 Market Street, Philadelphia, Penn.; The Philadelphia Lawn Mower and Lawn Sweeper.—JOHN LAING & SONS, Forest Hill, London, S. E., Eng.; Special Catalogue of Caladiums.—NATIONAL HOT WATER HEATER CO., Boston, New York, Chicago, San Francisco; The Spence Hot Water Heater for Heating by Hot Water Circulation.—BENJAMIN RIMBAUD, Toulon (Var), France; Special Trade Offer of French Bulbs for Forcing.—SHADY HILL NURSERIES, Cambridge, Mass.; Illustrated Catalogue of Choice Trees, Shrubs, Vines and Plants. Supplement of New and Rare Plants.—C. THURSTON, Paterson, N. J.; Price-list of *Begonia Thurstonii*.—THOMAS S. WARE, Hale Farm Nurseries, Tottenham, London, Eng.; New Catalogue of Hardy and Greenhouse Climbing Plants, Single Roses, Rare Fruits, Culinary Roots, etc. Illustrated Catalogue of *Paeonies*, *Primulas* and Hardy Ferns. New Catalogue of Hardy Florists' Flowers. Illustrated Catalogue of Hardy Perennials.—THOS. W. WEATHERED'S SONS, 244 Canal Street, New York, N. Y.; Hot Water Heaters, for Heating Dwellings, Conservatories, Greenhouses, Graperies, Poultry Houses, etc.

GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.

OFFICE: TRIBUNE BUILDING, NEW YORK.

Conducted by Professor C. S. SARGENT.

ENTERED AS SECOND-CLASS MATTER AT THE POST OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, APRIL 6, 1892.

Public Indifference to Forests.

THE greatest difficulty in dealing with large questions of national importance, whether political or economic, is to induce men to take an interest in any subject which does not personally and directly benefit them. Planning for future generations is not an occupation which is attractive to the ordinary mind anywhere. Large issues demand broad intelligence to cope with them and an amount of unselfish zeal which is not the endowment of everybody. The Prometheus of a generation is very apt to find himself chained to a rock, with the vulture of impatience gnawing at his vitals, while he chafes at the mistakes and apathy of his contemporaries, of which his clear vision foresees the consequences.

Public spirit that extends beyond the scope of one's vision, and has no connection with one's pocket or personal pride, is rare. One who pleads for what most people consider a sentimental cause has little chance with the promoter of a railroad scheme which gives immediate employment to many people and temporarily raises the value of land. He finds it easy enough to induce men to abate a nuisance at their own doors, but how many people are there who are capable of understanding the importance of preserving the forests on some mountain-slope in Colorado which they have never seen or even heard of? This anxiety besets him with regard to the blind destruction of forests, which goes on in spite of warning, in the teeth of entreaty, in the face of the proved fact that a more judicious management of our woodlands would result in direct pecuniary advantage even to individuals, while in a broad way it would render incalculable service in promoting the health and prosperity of the entire country. With all the abounding generosity which feeds and clothes and educates the needy, the world is still lacking in that larger benevolence which touches the roots of economic questions, and helps to ward off evils to come. Ready as we Americans

are with our pound of cure, it must be confessed that we, in common with the rest of mankind, are often niggardly enough about our ounce of prevention. The man of science, who sees consequences clearly, stands in the same attitude toward the destroyer of forests as a grown-up person does toward a child who is determined to grasp the flame of a candle, without the same power to prevent the consequences of ignorant rashness.

It is not our purpose here to point out in what way or to what extent a forest-cover on our mountain tops and slopes works beneficently, nor to show what disasters are sure to follow the destruction of such forests. There is much to be learned about these questions, but we know enough to demonstrate the folly of the reckless destruction of our woods. We are not called upon to base our action upon untried theories. Experience, and the most costly experience, too, has amply demonstrated what a nation loses when the wood-cover is stripped from its mountains, and what it costs to restore the wholesome balance of natural forces when this is once disturbed.

It is not knowledge that we lack. We have enough of this to form the basis of wise and successful action in saving and using our forests. The questions which the nation should now be discussing are the practical details of forest-management—that is, we should have proceeded far enough in this work to be studying and experimenting as to the most economical and effective system of forest-management under American conditions. Long ago public opinion should have compelled the laying of the foundations of a proper forest-administration for the lands of the nation and for the control of the forests under the various states. But, as a matter of fact, we have not begun to do anything; we have not begun even to get ready to do anything. To our congresses and legislatures warnings of destruction and depopulation such as have occurred over large territories of the French Alps sound like tales of little meaning. The result is that we still need exhortation by forest-congresses, and bulletins from the half-supported forest-bureau of the Government, and the pleadings of special writers in the newspapers; and all this not for the purpose of instructing the people in the most simple and elementary points of practical forestry, but to awaken them and their legislators to the fact that such a thing as forestry has an existence.

Of course, it is rather discouraging to know that the preliminary work, which ought to have been finished as early as the middle of the present century at least, will still be needed in the beginning of the next century. Other nations have waited for calamities to arouse them to the need of taking some thought for the future, and perhaps nothing less than a series of disasters will suffice to convince us of the necessity of some intelligent forest-policy. And yet such effort cannot be wholly wasted. A few will listen, and now and then one will be convinced, and ever after he will carry about the burden of his responsibility and become a centre of good influence. All this preparatory work will make the ultimate change in public opinion more radical and complete. The day is sure to arrive when we shall look back upon the reckless attacks upon our forests with torch and axe as the work of barbarians. It is literally true that, as a rule, we show no more prudence in our treatment of our forests than is manifested by the savage who, after supplying his present needs and satiating his appetite, lies down under a tree and sleeps with no thought or care for the morrow.

THE flowers of early spring have a peculiar charm. Every year as they open they bring a fresh delight, not only by their rare beauty, but by the appeal they make to the imagination as the pioneers of the great floral procession which is to sweep onward until arrested by another winter. These flowers attract our sympathies, too, by their singular delicacy. Nothing is so fragile as a Snowdrop, and yet its spirit is sturdy enough to brave the ice of February, and the dainty colors and tender grace of all of

these very early flowers are the more impressive because we do not naturally associate such a delicate exterior with the stout-heartedness which is needed to withstand the wild weather of an American March.

Of course, it is too late now to make any preparation for enjoying these flowers this year, but this is the time to make notes of them and to determine that the opening days of next spring shall be brightened by their presence. In this latitude Snowdrops are still doing well, and their vestal white is well set off by the blue of Scillas and Chionodoxas. Then there are Grape Hyacinths, Crocuses, of course, and a few of the *Præcox* Daffodils, the Irises, of which Mr. Gerard wrote so entertainingly last week, the comparatively new but invaluable *Anemone blanda*, Rock Cress, Winter Aconite and many more of rare beauty, which appear while the chill of winter is still in the air and before the coming of the burst of bloom from the great mass of spring flowers. It is well to remember that for very early flowers in our climate bulbous plants are better than fibrous-rooted ones, which, from their structure, are liable to be heaved out of the ground by alternate freezing and thawing.

MONSIEUR NAUDIN, in a personal letter from Antibes, calls our attention to the fact, of which we have long been aware, that Sabal Palmetto, the tree Palm of the south Atlantic states, is not to be found in any of the gardens of southern France, where, he remarks, it ought to be much hardier than many of the Palms which flourish there, as neither sun, the neighborhood of the sea nor the character of the soil is wanting, and then asks, "Can it be possible that the absence of this plant from European gardens is due to the absence of favorable microbes or to the presence of injurious microbes?" Sabal Palmetto is the most boreal of all the arborescent Palms; it must have been introduced into Europe a century or more ago, as Mark Catesby was familiar with it and sent many Carolina plants to England in the last century, as Michaux did forty years later to France. Perhaps some of our correspondents will be able to enlighten us as to whether this Palm is ever cultivated either in the southern states or in Europe where it is represented, so far as we have observed, by a single plant of exceedingly doubtful identity in the Palm-house at Kew.

The Story of a Suburban Place.—II.

THE shaping of the surroundings of the house has been a matter of slow and gradual progress. The work is by no means completed yet, and the contemplation of the opportunities for adding pleasant features is no small source of enjoyment. Nature has done much toward the plan, and the main idea has been to re-enforce and assist her in the creation of an attractive scene. The character of the ledge beside the house, being rough and wild, forbids anything like decorative regularity, and the treatment adopted has therefore kept in view the idea of blending and modulating the ruggedness into an environment of informal domesticity.

The entrance to the place, serving the neighboring house as well, was originally along the easterly boundary of the lot. After a while the hand of municipal improvement was laid upon our lane and its steep and stony ascent was changed into a handsomely curved and well-graded public street. This was welcome, for the lane had been a cause of protest on the part of local hackmen, and in the winter the overflow from a spring farther up the hill had at times converted its gullied slope into a glacier. But, unfortunately, the improved grade had so cut it down that the beginning of our entrance was left so far above the sidewalk as to require an appallingly steep ascent if kept upon the old lines. So the best thing to do appeared to be to buy something over 13,000 feet of the neighboring land and construct a new drive-way, curving up the hill-side.

This drive-way skirts the verge of a thicket of wild wood that occupies the upper portion of the new land. It is a picturesque clump of trees, though promising no luxuriant growth, for the most part, on account of the dryness and rockiness of the hill-side. There are White Oaks and Red Oaks, White Ash, Hornbeam, Red Cedar, Pitch Pine, Wild Cherry and Tame Cherry, the latter evidently sprung from seed sown

by the birds. On the lower side of the drive-way is a Tupelo, something of a rarity in these immediate parts.

The grade of the drive-way is so steep that attempts to keep it in order have been fruitless. Cinders from the furnace have given it a firm surface for a while, but a severe down-pour washes it badly. Nothing but paving would give it anything like permanent orderliness, and as that would be too costly the best thing appears to be to let it alone. It is not much used, except for heavy deliveries, and so it is allowed to take on the appearance of a rural lane, which is not out of keeping. The undergrowth of the woodland thicket largely supplies its borders. The upper slope forms a bank of Barberries, Blueberries and Privet, and the wild Fox Grape—bearing abundantly its clusters of small-berried and big-seeded fruit, of little value except to attract predatory urchins, who fancy that the wildness of the spot gives them license to help themselves—climbers in tropical luxuriance over the trees above. The road-way is fringed with Wild Primrose, Asters, Golden-rod and other spontaneous growths. At one spot a mass of Black-berry-canecanes, with a sort of Bamboo-like grace, has grown as high as eight feet out of the irregular stone embankment on the lower side of the drive-way. These are beautiful at all seasons, and particularly so in the spring, with their wealth of blossoms.

At the turn of the drive-way, a glimpse of the house is caught, with a large Savin as a sort of sentinel outpost at the beginning of the open ground—a picket from a grove of the same trees, which, though on another lot of land, form a kind of adjunct to the place. They are, fortunately, so situated that they will be likely to remain. The Savin, or Red Cedar, like the European Cypress, has a sort of architectural character, with its spire-like form, and often lends itself beautifully to the effect of buildings near by, as in this case.

A recent survey shows a practical approach by a slightly curving drive from the same direction as the original entrance, with a grade even lighter than that of the street. When the new drive-way is constructed the existing one will probably lapse into a foot-path. Where the present drive-way meets the street the latter makes a short curve, forming an excellent corner lot on the more recently purchased land. Here a thicket of Sumachs has sprung up. In constructing the street a fill was made here, and the rich soil from the surface chances to make a considerable bank along the hollow, next the sidewalk. Here a charming wild garden has come into existence. A dense growth of Bouncing Bet has established itself, and above, next the sidewalk, there is a margin of Chicory, which is one of the European plants that has naturalized itself in the country around Boston, bordering the suburban and country roads most profusely. The Chicory in this spot grows luxuriantly and remarkably high in the fertile soil. So all summer long the slope is clothed with a delicate flushing pink, contrasting delightfully with the cloud of azure bloom into which it merges above.

Close beside the house, to the northward, rises the gray ledge of the hill-side, which gives shelter from the cold winds of winter and makes a local climate which, in the inclement season, is several degrees warmer than on the levels where the main street runs. This ledge is a most picturesque feature. Three Cedars stand upon its verge, and on the slope next the house is a mantling growth of Privet, Barberry and Wild Rose entangled with Wild Grape and Virginia Creeper. The Privet and Barberry are beautiful examples of the "escaped" flora that has established itself in this part of the world. They grow in untamed luxuriance, as to the manner born, and are beautiful at all seasons except, in the case of the Privet, for the brief interval in which its blossoms turn rusty. The Privet, happily, offers no temptations with its fruit, but unceasing vigilance has to be exercised in behalf of the Barberries, whose graceful pendulous clusters gleam like rubies all through the winter against the gray surface of the ledge—fringing it above or growing out of its crevices. For, being "wild," wherever it may grow, it is regarded as a legitimate plunder for foraging boys, who take to the woodlands with their bags and baskets for the Barberry harvest. In the code of the populace all wild fruits constitute an "unearned increment," to which the owner of the soil has no rightful title. Usually a few bushes along the ledge pass through the harvest season unspoiled, and, until the yellow blossoms again droop in their exquisite curves late in the spring, the Barberries form an enchanting spectacle under all aspects of the day, the season or the weather, and from all points of view—flashing in the sunlight or illuminating the dullness of an overcast day, vivid against the snow, contrasting against the blue of the sky, or, seen through the vagueness of a fleecy mist, they become gorgeous jewel-clusters as they drip with diamond damp. Last

winter the Barberries were parties to some enchanting effects in the phenomenal ice-storm, and in that damp, soft clinging snow that clung through the calm air of two or three days.

Along the foot of this ledge remained a bank of gravel, which was covered with soil and planted with a carelessly disposed growth of shrubbery—*Symphoricarpos vulgaris*, the Bayberry, Wild Rose, Staghorn and Glossy-leaved Sumach, Elder, Japanese Barberry, Japanese Honeysuckle, and an example or two of other species. Next the path is a border of Periwinkle. One portion of the ledge is faced with a luxuriant growth of the variegated-leaved variety of the Japanese Honeysuckle, whose golden tone contrasts agreeably with the darker foliage around. Over another portion a Japanese Ivy clings, and an English Ivy, which is perfectly hardy on other ledges in the neighborhood, has made a good start. Elsewhere the clinging *Eunoymus radicans* is growing slowly. The whole effect is that of a natural growth that adapts itself admirably to the ruggedness of the ledge. Here and there some spring bulbs—*Scilla*, *Narcissus*, *Jonquil*, etc.—give beauty to the ground before the foliage appears, and, where room has permitted, some hardy perennials, like *Phlox* and *Loose Strife*, brighten the leafage with masses of color in the summer. Sunflowers and Poppies, from seeds thrown carelessly, also spring up in places where opportunity offers.

The space of turf borders the drive-way with a grassy bank, and here the first flowering bulbs of spring-time sprinkle the tender green with their welcome bloom—*Crocus* and *Snowdrops*, followed by *Scilla*. Here, also, a diminutive water-garden has given such satisfaction as to cause a desire for an expansion, as aforesaid. It consists of the two halves of a linseed-oil barrel, burned out and set in the ground, side by side. In one a *Lotus* has flourished superbly, with its great velvety leaves and exquisite blossoms of blushing rose-tipped creamy petals. In the other, for two years, a fragrant white *Water-lily*, the common *Nymphaea odorata*, bloomed profusely for two summers; but, unfortunately, acting on the advice of some one who said he had left a *Water-lily* out in a tub over winter the year before and it had proved perfectly hardy, when spring came it did not make its appearance. This season the place of the *Water-lily* was occupied by the floating plant known as the *water Hyacinth*, which, from a single example, spread so rapidly as soon to crowd the tub. Out of this growth there rose the graceful shape of a *Calla*. With the pure, waxen-white flower of the latter surrounded by a mass of the delicate lilac-colored spikes of the *water Hyacinth*, and the noble foliage and queenly flower of the *Lotus* adjacent, the spectacle was enchanting.

The house is dressed with *Virginia Creeper*, *Japanese Ivy*, *Clematis*, *Wistaria*, *Japanese Honeysuckle*, and a *Bittersweet* from the neighboring woods. With these mingle some climbing annuals, like *Morning Glory* and *Canary-flower*. For a flower-garden there is not, as yet, so much space as one might think, for where there is the most room it would appear incongruous, and the *Apple-trees* shade an otherwise most appropriate place. As these serve to screen prosaic features of the neighborhood, it would hardly do to cut them away. The flowers are therefore, for the most part, confined to the immediate neighborhood of the house. In the shade of the northerly side a bed of tuberous *Begonias* has given much delight with their wealth of large and richly colored flowers of many shades and hues—crimson, scarlet, vermilion, lemon, straw color, cream and white. A most exquisite variety is a delicate yellow, with the tips of its petals flushing into rose.

The steep and dry southerly slope of the premises has not yet been touched. From the house the eye is carried at once into the distance by the broad prospect Bostonwards, and the ground falls away so abruptly that it is overlooked. Here a few utterly neglected *Pear-trees*, pathetic in their awkwardness, persist in pleading for their lives with such abundant annual offerings of their fruit—loyal to the reputation of the surroundings of Boston as the finest *Pear-country* on the continent—that they have been spared. This slope would probably make an excellent vineyard, or perhaps even a vegetable-garden, if one could afford that luxury. One proposition that commends itself is to establish a growth of trees on the lower portion to shut out the main street and the backs of its bordering houses—the sight of which might some day become unpleasant, though not so now—and to carpet the remaining space with flowering shrubs and hardy perennials, which should bloom in succession through the season.

The southerly slope of a neighboring unimproved tract to the westward immediately adjoining is rapidly reverting to wilderness, and if left untouched a few years more will see a flourishing young forest there. May it long remain so.

Boston.

Sylvester Baxter.

Holiday Notes in Switzerland.—III.

FROM Münster, which we had reached when this record was interrupted, we went by diligence to Fiesch, and thence on foot to Brieg, which is 2,224 feet in altitude. As might be expected from the decreasing elevation, few plants belonging strictly to high altitudes were noticed. *Selaginella Helvetica*, a pretty rock-plant in English gardens, was seen on the banks skirting the road near the Bridge of Grenchols, and from the bridge itself, on ledges in the ravine much too far below us to allow of our recognizing the species, we saw huge masses of *Solomon's-seal* (*Polygonatum*). On sunny exposed banks *Dianthus Carthusianorum*, with clustered heads of red flowers, and *D. sylvestris*, with solitary rose-colored flowers, were not uncommon. Both are charming plants, which thrive under cultivation, and are worthy of a place in every rockery. *Lactuca perennis*, a beautiful composite with pale blue flower-heads, grew in company with the two last-named plants. On walls and rocky banks *Sedum reflexum* and *S. album* were noted in great abundance, but neither species was in flower at the time of our passing. On the banks of the Rhone the long compact spikes of *Veronica spicata*, rising from a carpet of gray-green leaves, and clumps of *Prunella grandiflora* attracted attention by their showy blue flowers. The two are excellent garden-plants and easily grown. *Coronilla varia* formed masses of rich green, enlivened by numberless heads of white and lilac pea-shaped blossoms. This is an excellent perennial for dry banks. *Vicia sylvatica*, with lax racemes of whitish flowers lined with violet, is another perennial both pretty and graceful. The *Bladder-senna* (*Colutea arborescens*) was abundant. In Swiss rustic practice its leaves are sometimes substituted for senna as a purgative. *Hippophae rhamnoides* and *Myricaria Germanica* both grew along the Rhone—in some spots out of chinks in huge masses of rock in the bed of the river itself.

From Brieg, a beautifully situated little town and a railway terminus, we took train to Sierre, an interesting town, one of the most famous of the Swiss "grape-cure" stations. The climate here is favorable to convalescents and to sufferers from bronchial affections. Good wines are made in the neighborhood.

At Sierre we left the Rhone Valley and its vineyards and began at once to ascend the Val d'Anniviers above the narrow inaccessible gorge of the Navigenze. Fine forests, principally of Scotch Pine and of Norway Spruce, occur on the steep slopes; on the first-named, the *Mistletoe* (*Viscum album*) grew in abundance at the mouth of the valley. The *Virgin's Bower* (*Clematis Vitalba*) climbed high up the trees among the rocks below the road, and the *Everlasting Pea* (*Lathyrus latifolius*) was also not uncommon. In clearings, some not a dozen yards square, on ground so steep that the manure necessary for the rye and other crops has to be carried in baskets on men's backs, the peasants were busy turning over the soil. Before we had proceeded far up the Val d'Anniviers we came upon some of the "bisses," or irrigation canals, which form so striking a feature in many places in the canton of Valais. As Dr. Christwell says, in his *Flore de la Suisse et ses Origines*, these "bisses" excite the wonder of every one who for the first time visits the Valais. They represent a sum of work and perseverance which gives the highest idea of the energy of the inhabitants. These works cede in nowise—as regards extent—to those of the dykes and innumerable canals of the rice-plantations of Piedmont, and they surpass them much in boldness of execution. The "bisses" often descend from the very foot of the glaciers, for it is only from there that, in the middle of summer, a constant supply of water can be depended on; even in the upper mountain regions the glacial torrents hollow out a bed for themselves in gorges so deep that it is often impossible to get at the water. The wooden troughs are often carried along on wooden or iron supports which the workmen have had to fix into the vertical or overhanging sides of precipices while suspended at the end of a long rope. The commune of Mund, for example, had to procure a rope 1,200 metres in length to enable it to carry out its own irrigation system. Without these wonderful constructions many districts in Valais would be completely burnt up in summer, and a good deal of high ground, now of great value for grazing, would be absolutely useless. In the lower districts, hill-sides, now of considerable value as vineyards, could not be used for any purpose without this constant supply of water. The excessive dryness of the climate of Valais will be understood when it is stated that it is necessary to water the vineyards—in most parts of Europe the Vine suffers from too much water rather than from too little.

Among many handsome plants noticed between Sierre and Vissoye were *Teucrium montanum*, a dwarf-growing spe-

cies with large yellow flowers, which thrives in English rock-gardens; *T. chamædrys*, a taller grower with smaller rose-colored flowers, and *Artemisia vallesiaca*, a very rare and graceful plant, with finely cut ashy gray leaves. *Anemone Hepatica* was easily recognized by its leaves. *Ononis rotundifolia*, a species with large rosy red pea-shaped flowers, and *O. Natrix*, with large yellow flowers, were conspicuous in sunny spots on banks; both are good garden-plants in Britain.

Kew.

Geo. Nicholson.

Serotinous Pines.

OF the thirty-seven species of Pines found within the borders of the United States, a small group are somewhat peculiar in the development and persistence of their cones. As is well known, most Pines mature their cones in about two years—i. e., the incipient cones of one spring become fully developed in the fall of the second year. The period of ripening usually begins about October, and if the weather be dry and warm the cones soon afterward begin to open and the seeds to be liberated. From then on till spring the cone-scales continue to open and close under the alternating influence of warmth and moisture, and with one or two northern species a large quantity of seed is liberated only after the snow has departed and the sun is again sufficiently warm to thoroughly open the cones.

The Pines having their leaves in fascicles of five, a group in which the White Pines naturally fall, are doubtless the least tardy in shedding their seeds, as they are least tenacious in holding their cones; few, if any, seeds or cones survive the shedding process which nature subjects them to during the first winter.

In the group *Tæda*, two and three-leaved Pines, comprising about twenty species, mostly southern and western, it is not uncommon, however, to find cones persisting on the trees for eight to ten years. The most striking examples of this peculiarity are seen in the following species: *Pinus contorta*, *P. Murrayana*, *P. muricata*, *P. tuberculata*, *P. insignis*, *P. Virginiana*, *P. clausa*, *P. rigida*, *P. pungens* and *P. serotina*. Among these species may be specially mentioned *P. clausa*, *P. serotina*, *P. tuberculata* and *P. insignis* as additionally remarkable for retaining their seeds long after the cones are mature.

Michaux was doubtless the first to observe that the Pond Pine (*P. serotina*) of the southern states matures its cones in two years, but does not liberate its seeds till the third or even fourth year. The closely allied Pitch Pine (*P. rigida*) of the north Atlantic region, though producing less commonly serotinous cones, frequently retains its seeds for a considerable time after the cones are mature. Latest, perhaps, among the discoveries of eastern serotinous Pines is the Florida Spruce Pine (*P. clausa*), in which the seeds are retained at least three or four years. The cones of some individuals of this species, an illustration of which is given on page 161, are not without exception in sometimes opening at or soon after maturity (Fig. 24, *c*), while others ordinarily remain closed for a longer period; occasionally cones are found in which the seeds ten years old have apparently not been liberated.

Of the eastern serotinous species the Florida Spruce Pine is moreover most interesting in the persistency with which it retains its cones. They are so strongly attached by a tough woody columella that the growing tissue of the trunk or branch rarely forces the cones off, but in time commonly envelops them, as seen in *h*, Fig. 24. The important stages of persistence following the mature open cone (*c*), to the deeply-imbedded cones (*h*), are successively illustrated in *c*, *f* and *g* of the figure.

It may be of interest here to recall the note published twelve years ago by Dr. Engelmann (*Bot. Gazette*, v., 62, 63) on the vitality of seeds from the serotinous cones of *P. Murrayana*, a Pacific Coast species. The cones were collected in Colorado in 1875, and after being kept in a dry garret for about five years were sent to Professor Sargent to experiment with as to their germinating power. Seed from cones five years old did not germinate. Seeds still older germinated and grew up, as follows: One out of four six-year-old seeds, one out of three seven-year-old, one out of eleven eight-year-old, one out of six nine-year-old. Seeds from cones ten and eleven years old did not germinate, although such seeds were perfectly sweet and apparently sound.

Dr. Engelmann remarks that the above result was not considered satisfactory; his own opinion, however, being that the result was highly satisfactory, showing that seed in cones five to nine years old retained their vitality, while seed from those over nine failed to grow.

These experiments, doubtless, indicate clearly enough that the life of serotinous Pine-seeds may be trebled, if not quad-

rupled, by being kept in the cones, as compared with shelled seed preserved under the same dry and certainly most unfavorable conditions, it being well known that the germinating power of shelled seed rarely endures longer than two or three years, and usually fails for any considerable per cent. of germination even earlier than this. Why the seed from five-year-old cones did not germinate is not clear, for it is not probable that the younger seed should possess the greatest vitality. The whole subject suggests the need of experiment on the length of time which may elapse before these cones open and during which the seeds retain their vitality.

The degree of heat and moisture to which the cones are subjected doubtless has much to do with the question of early or late opening; this in turn being determined by the season. The comparative effects of these elements are illustrated in the behavior of ripe cones of *P. clausa* subjected to different degrees of heat. Cones left out-of-doors during one season have not opened, but those kept in a covered box in a room with temperature ranging from sixty-eight to ninety degrees, Fahrenheit, opened within two months (*c*, Fig. 24), while cones five to seven years old have not opened under either set of conditions. Cones of *P. serotina* have also behaved similarly under the same conditions.

But it is a noticeable fact with almost all serotinous species that a few cones may be found on nearly every individual which open at or soon after maturity, this early opening occurring most frequently on the south and east sides of the crown; occasional opening of this kind may be observed for two to three years after maturity, so that all individuals and species of this class cannot be said to be uniformly serotinous until at least some seeds are shed. The amount of seed liberated at one period of opening is often quite small, the majority of the cones appearing to remain closed.

In seeking for the special economy which nature seems to aim at in imposing upon certain species of Pines the necessity of keeping their seeds over indefinitely, or the mechanical hindrance to shedding them at maturity, it would be interesting to discover how far in reality this peculiar ability or disability is of advantage in perpetuating the species. It would seem quite improbable that for a most perfect germination the seeds should thus be housed for several years before being allowed to escape, as if by retention it were necessary for the seeds to undergo some as yet unknown physiological change, such as that required by certain fungus spores which are unable to germinate until they have passed a winter in the open air. For the seeds of *P. clausa* this is certainly not necessary, as those extracted from mature cones two years old germinated immediately.

There is very little chance of the most persistent serotinous cones reaching the ground, in the ordinary course of events, within eight to ten years, and if they did, they would be likely to open more tardily still; and seed so confined would doubtless become spoiled before the cones were sufficiently decayed to liberate it.

With the exception, perhaps, of *P. serotina*, our serotinous Pines naturally inhabit dry and sometimes nearly arid localities. It may be, therefore, that some advantage accrues to such species in not being able to lose all their seed at once; the actual process of serotinous species being to give up only a few seeds at a time, and thus make the most of their chances to secure conditions favorable for germination. Many other Pines not strictly serotinous, inhabiting similar dry and arid regions, seem to follow the same plan of tardy shedding of seed.

The little-known Florida *Pinus clausa* is geographically somewhat confined in Florida, ranging only from the western border of the state southward along the coast, usually not over thirty miles inland, to the Cedar Keys, where Professor Sargent found it growing quite abundantly. It occurs also on the Atlantic side, south of St. Augustine, here occupying only a narrow ridge of sandy upland as far south as latitude twenty-nine degrees. For the most part it seems to take kindly to the pure sand wastes of the Florida coast, and is here rarely ever more than fifteen to thirty, occasionally forty, feet in height, with a diameter under twelve inches, and branches often coming down quite to the ground. It is not uncommon along these sand-dunes to see numbers of these trees bent over or uprooted by the strong autumnal gales, the yielding sand not affording sufficient support for the roots. On higher ridges and uplands, where the sandy soil is richer from an admixture of clayey marl, it becomes a much larger tree, and is associated with deciduous-leaved trees (Hickories, Oaks and Magnolias), here attaining a height of fifty to seventy feet and over, with a trunk-diameter of more than eighteen inches. In the region of Halifax Bay finely developed specimens of this Pine are still to be

D. Olszewski det

a. A branchlet with male flowers. b. A branchlet with young cone, first season. c. Cone two years old, opened by artificial heat. d. A scale and seeds. e, f, g. Persistent closed cone, 4-6 years old. h. Cross-section of a branch surrounding the base of old cones. All natural size.

seen, with trunks thirty to forty feet in length free from branches. These more perfect specimens somewhat resemble *P. glabra*, and among the natives often pass for that tree under the common name of Spruce Pine.

The coarse bark of the trunk is brownish, scaly, and not unlike that of its northern relative, the New Jersey Scrub Pine; but is strikingly different from the latter in the smooth cinereous bark of its upper stem and widely spreading branches. Other important features of this Pine which readily distinguish it from the New Jersey Pine are its longer, persistent, gray, closed cones, and its less rigid and thinner leaves. The cones are also more strongly reflexed than in *P. Virginiana*, while the involucre bracts are ten to eleven in *P. clausa*, and only eight to nine in *P. Virginiana*. The cotyledons of the latter are five to six, as opposed to four (occasionally five) in *P. clausa*.

At the present time the light soft timber of the Florida Spruce Pine has no particular economic value aside from small and very local consumption. The thick, nearly white, sap-wood of the younger trees is often rather coarse-grained, especially in open stands; the heart-wood, commonly less in quantity than the sap, is of a light orange color, and in the larger specimens of rather fine and even grain, resembling that of *P. echinata*. The rare ability of this species to maintain itself with a degree of certainty on the pure sand-wastes of the Florida coasts must doubtless recommend it as a most important element for the future reforestation of these and other adjacent timberless barrens.

A few notes on the synonymy of this Pine may be of interest in this connection, since its botanical name is involved in some misapprehension as to its rightful author.

P. clausa was first discovered at Apalachicola, Florida, by Dr. Chapman in 1846, and twenty-three years later was included in the first edition of his *Flora of the Southern States*, first as *P. clausa*, then as *P. inops*, var. *clausa*, but finally discarded, before the work was published, on the ground that it was only a form of the northern Jersey Pine (*P. inops*). Dr. Gray, however, revived the forgotten species in 1875, when he saw it for the first time in a visit to Florida, later bringing it to the notice of Dr. Engelmann, who studied it carefully, and published his notes in 1877 and 1880.

But the first notice of this species appeared in May, 1876 (*Gardeners' Monthly*, xviii., 151), in a communication by Dr. Vasey entitled "Trees of Southern Florida," a list of Florida woods collected and transmitted by Dr. Chapman to the Department of Agriculture for the approaching Centennial Exhibition. The note is as follows: "*Pinus clausa*, n. sp., at Apalachicola. Dr. Engelmann is doubtful. Perhaps it may be a variety of *P. inops*." Dr. Vasey disclaims the responsibility of naming *P. clausa* in a note preceding this list, in which he says: "I append Dr. Chapman's list of trees obtained (modifying the arrangement)."

Later in the same year Dr. Vasey published the next account of this Pine:

"*Pinus clausa*, Chapman, Florida. A small tree found by Dr. Chapman at Apalachicola, related to *P. inops* (*Cat. For. Trees*, 30; *Rep. Com. Agr.* for 1875, 178. 1876)."

In 1877 (*Bot. Gazette*, ii., 125) and in 1880 (*Trans. St. Louis Acad. Sci.*, iv., 183) Dr. Engelmann gives us the first technical diagnosis of this Pine under "*P. inops*, var. *clausa*."

In his preliminary *Catalogue of Forest Trees* (1830), under *P. inops*, Professor Sargent says of this species: "A variety with serotinous cones (*P. clausa* and *P. inops*, var. *clausa*, Chap.) has been detected in Florida by Dr. Chapman."

In 1883 Dr. Vasey gives the fourth notice of the Spruce Pine under *P. inops*: "In Florida a variety of this species occurs (var. *clausa*), which has narrower leaves and larger cones, and the cones frequently remained closed on the tree for several years (*Am. Journ. For.*, i., 164)."

In the *Catalogue of Forest Trees of North America* (*Reports, Tenth Census*, ix., 75) this Pine is designated as "*Pinus clausa*, Vasey, *Cat. For. Trees*, 30," "*P. inops*, var. *clausa*, Engelmann," being cited as a synonym.

In his supplement to the *Flora* (1887) Dr. Chapman follows Engelmann, giving "*P. inops*, var. *clausa*, Engelm."

The notes here given conclude the main bibliographical ordeal of this Pine since its discovery, and have been reproduced to help clear up the synonymy and substantiate a necessary change in the authorship of *P. clausa*. Regarding this point, it will be seen from the various accounts cited that *clausa* was first properly established by Dr. Engelmann (l. c.), and that in now considering it a species, Professor Sargent, being the first to properly publish it as such, is responsible for the combination *P. clausa*, in virtue of having cited (l. c.), as an equivalent, Engelmann's name, the earliest one accompanied by a diagnosis. This may appear unjust to the original dis-

coverer and those who much earlier published the name *P. clausa*; but the decision is in accordance with the laws of nomenclature and current usage. Employing the double citation the name will become *P. clausa* (Engelm.), Sargent; or *P. clausa*, Sarg., after the De Candollean usage.

It is, moreover, evident that "*P. clausa*, Chapm.," Vasey in *Gard. Month.*, l. c.; *Cat. For. Trees*, l. c.; *Rep. Com. Agr.*, l. c. (1876); "*P. clausa*, and *P. inops*, var. *clausa*, Chapm.," Sargent, *Prelim. Cat. For. Trees*, l. c. (1880), and "*P. clausa*, Vasey," Sarg.; *Tenth Census*, l. c. (1884), can be regarded only as *nomina nuda*, being published with no characters, and accordingly not entitled to recognition.

Winter Climbers.

SOME of our best greenhouse climbing-plants may, with judicious treatment, be made to flower freely at this period of the year, when they are specially acceptable and useful for clothing walls, columns and rafters. The Allamandas, for example, will continue to grow and blossom as long as water is supplied to their roots, and their gorgeous, rich golden flowers are always pleasing. These plants, however, give best satisfaction when allowed a season of complete rest. Summer and autumn is their proper flowering time; when this is prolonged into winter, the plants should be kept perfectly dry for a few weeks in spring, and pruned moderately close a week or so in advance of starting them, in order to insure a good crop of flowers during the following season. *A. nobilis* and *A. Schottii* are perhaps the best kinds for general use; they require a soil of good substance, plenty of space for their roots, and a stove temperature.

A plant of similarly energetic habit is *Bignonia venusta*, one of the choicest of exotic climbers. It is very floriferous, producing large terminal trusses of vivid orange trumpet-shaped flowers from September to April. Plenty of space should be allotted to the branches, as they flower to greater advantage when given full freedom. Ordinarily good soil will suffice for the roots, and the house should be kept moderately warm in winter.

The Cherokee Rose (*Rosa lævigata*) is in full bloom now, having been pruned in January. It is a glorious mass of dark green leaves and large pure white flowers, with a conspicuous ring of yellow stamens in the centre. The buds are beautiful, and are borne in such profusion that the plant often becomes a sheet of snowy whiteness when they open out. The pity is that they last but two or three days after full development. This plant is a rampant grower, and the wood must be thoroughly ripened before it will flower well. Full exposure to sunshine is therefore essential, as is also an unlimited supply of air during warm weather. Although thoroughly naturalized in the south, it is not hardy in this latitude. *R. lævigata* is well worth a place in a large house, where it can be planted in an inside border. It blooms about April in its native state, but in a house affording an intermediate temperature the flowering period may be regulated easily by pruning. A dressing of decayed manure applied to the soil after pruning is highly beneficial.

Thunbergia laurifolia is a vigorous climbing shrub which was introduced from the Malay Peninsula in 1856. The large, opposite, petiolate leaves are of deep green color and oblong-lanceolate outline. The flowers are three inches in diameter, the limb five-lobed and of pale blue color, the tube wide, pale yellowish inside, and white on the outside. They are borne profusely, during the autumn and winter months, in terminal or axillary racemes or whorls. *T. laurifolia* Harrisii is even more attractive than the type, the flowers being of a deeper shade of blue with throat of orange-yellow, and they appear in still greater numbers. It is a native of Moulmein, whence it was introduced about the same time as the species. Both plants flourish luxuriantly when grown in a house the temperature of which is not allowed to fall below fifty degrees, Fahrenheit. The roots, however, should be confined as to space, or the growth becomes rank and the quantity of flowers is lessened; for the same reason, the soil should be of a medium rather than a rich character. Even with these precautions it is frequently necessary to thin out the thick mass of branches.

Kennedy rubicunda is not so well known as the foregoing, although it is more than a century since it was introduced from Brazil. It is an evergreen twiner, growing and flowering freely in a cool house. The trifoliate leaves are of bright

green color, and the papilionaceous flowers rich red, tinged with black in the lower portions, and borne in axillary clusters. The flowers have an odd, but by no means unattractive appearance, and the plant is easy to grow, thriving in common potting soil. Fitting companions to this, requiring similar treatment, are *Solanum jasminoides*, with its innumerable pendulous clusters of pure white star-shaped flowers, each having a showy bunch of yellow anthers in the centre, and the graceful, thrifty *Tecoma australis*, whose yellowish tubular flowers, with brownish throat, are produced abundantly in large drooping panicles. *Manettia bicolor* must not be forgotten, for its yellow-tipped, bright scarlet flowers have a matchless way of imparting brilliance to dull old walls. The list is far from being exhausted, but a sufficient number have been mentioned to show what can be accomplished in this direction without much trouble.

Cambridge, Mass.

M. Barker.

Odontoglossum Rossii.

WITH the exception of *Odontoglossum crispum* and *O. Pescatorei*, there is, perhaps, no representative of the genus so generally useful as *O. Rossii*. In 1837 the collector Ross introduced this species from Oaxaca, in Mexico, to England, where it was placed in the hot-houses of his patron, Mr. Barker. Usually from three to five flowers are borne on the more or less arching scapes. At a recent show of the Royal Horticultural Society in London a plant was exhibited, on one scape of which, a branched one, as many as fifteen large flowers were fully expanded. The variety, which had been grown in the collection of Mr. Philip Crowley, Waddon House, Croydon, was an exceptionally good one. The sepals were heavily blotched with chocolate-brown on a cream-colored ground, while the petals and lip were of a beautiful soft pink, delicately veined with rose. At the base the petals were, of course, heavily blotched like the sepals, and the clear lemon-colored callus, streaked at the sides with red, gave the whole a soft and charming appearance.

Amateurs about to undertake the culture of a few choice and easily grown Orchids could not do better than include several plants of *O. Rossii*. Fair, healthy pieces may be obtained as low as half a dollar, although exceptionally fine varieties sell much higher. *O. Rossii* usually blooms during the coldest and dullest months of the year, and if proper treatment is given, the flowers will continue in a fresh unspotted condition for a considerable time. The plants thrive best in a light-some position; the best means to secure this is to grow them in small square baskets or pans, which can be easily suspended within a foot or two of the glass by wires. A compost of rough fibrous peat and clean fresh sphagnum, thoroughly drained, is suitable, and the winter temperature at night should not be allowed to sink below fifty degrees, Fahrenheit. Attention to watering is always necessary, larger and more frequent supplies being given when the plants are vigorously growing than when they are taking a rest and ripening off the pseudobulbs formed during the year.

Isleworth, London.

John Weathers.

Two New Poppies.

A VARIETY of Poppy called the Golden Gate, an introduction of last year, will please all who admire the Shirley Poppy, as it is an improvement on that favorite variety in size, general thriftiness, diversity of coloring, and in the length of its blooming-time.

Plants from seed sown May 23d began to bloom in two months, and grew to a height of three feet. The leaves are bright green, thin, gracefully curved and ruffled, and finely, though very irregularly, cut. They are somewhat hairy, and the blossom-stems are more so, being covered with a fine down, which is sometimes of a silky light red. The buds bend over upon the stalk in shepherd's-crook fashion, the loop thus formed measuring about two inches. The blossoms are single, semi-double, and more rarely perfectly double. The single ones, which are perhaps the most attractive, have four semi-circular petals, the outer pair of which sometimes open flat, making a shallow saucer, while the inner ones fold together and stand up like a cup. But this arrangement is variable.

As the larger blossoms opened they were measured, it being so much more satisfactory, as Thoreau somewhere says, to be exact, and not to say that a thing is "large" or "very large." There was a dark rich red one three and one-half inches broad. The flowers of this color were always single or slightly double, and had at the base of each petal a fan-shaped black spot edged with white. There was a bright cherry-red one, of the shade of color seen on some Japanese fans. This had a white mar-

gin, and measured three and one-fourth inches. Then a clear delicate pink, with white edge, of the same size; a double gray and red of two and one-fourth inches. All these colors in great abundance, as well as clear white, rosy lilac, small very double scarlet ones, and, most striking of all the combinations, a single one, of which the outer petals were scarlet, and the inner ones white, flaked with cherry.

All the Poppy-petals had a silky sheen and a beautiful creasing or crimping of their delicate texture, which was truly a delight to the eye. A stray plant coming up at a little distance from the others, and having room to develop, grew in regular bush-form, twenty-two inches high and twenty-one inches broad. When measured it had one blossom, two dry-seed vessels and twenty-seven buds. Its coloring was the reverse of the typical Shirley strain, being creamy white, with pink edges. The stamens are yellow in light-colored Poppies, and black or purplish in the dark red ones. One charm of the single blossom is its curious seed-vessel with the velvet star-like stigma, plum-colored velvet in the dark Poppies, and white in the others. The Golden Gate Poppies are in profuse bloom till the time of hard frosts, though the number has by that time dwindled to four or five fresh ones each day.

The Flag of Truce, also new last year, makes a wonderfully stout growth, a little over three feet in height. It has a ruffled fringed leaf, often ten inches in length, of a thick smooth texture like a cabbage-leaf, which it resembles in color. There is no down about any part of the plant. The bloom is single, white, shaped like a Tulip, a giant Tulip, for it is four inches across. The correspondingly large seed-vessel is white, with a green velvet stigma. The filaments are pure white, with clear yellow stamens, which soon turn brown. The blossom lasts only about six hours, the petals falling off early in the afternoon of the day it opens. One of the great petals was four and one-fourth inches across, and showed strong white veins. It is a curious Poppy, but it must extend the period of its "truce" before it will be thought very valuable as a garden ornament.

West Hartford, Conn.

Amy Whitman.

Nepenthes.

THE East Indian Pitcher-plants form one of the most interesting groups of ornamental-leaved plants now in cultivation, and are deserving of much wider distribution. *Nepenthes* require the conditions of stove foliage plants, a temperature of sixty-five to seventy degrees and a moist atmosphere. With sufficient heat and moisture but little difficulty will be found in their cultivation. The compost best suited to them is composed of rough fibrous peat and sphagnum-moss; a covering of living sphagnum is beneficial, and also improves the appearance. Wooden Orchid-baskets are useful for growing these plants, and display the curious pitchers to good advantage; these are not absolutely essential, and I have seen fine specimens grown in pots or pans; an abundance of drainage material should be supplied to those in pots to prevent their becoming sodden.

Propagation is usually effected by cuttings, or by seeds when they can be procured, but as these plants are dioecious, seeds are not common in the ordinary collection. Quite a large number of species are now known, and the genus has been much enriched by garden hybrids produced both in Europe and in the United States. Many of the first and finest hybrids on this side of the water were originated by the late James Taplin, who crossed several species sixteen or eighteen years ago; several thousands of seedlings were raised therefrom, many of which have since been named and introduced by various firms. It is difficult to select a short list from the many good forms now in cultivation; among those worthy of general cultivation are *N. distillatoria*. This old novelty is of strong and rapid growth, and produces large bright green pitchers; the stalks usually show a curl or half-hitch, and seem to indicate the tendril-like nature of these curious appendages. *N. distillatoria rubra* is an improvement on the type; the pitchers are frequently ten inches long and are suffused with red over nearly their whole surface.

N. Chelsoni was among the earlier hybrids produced in Europe, and originated at Messrs. Veitch's well-known establishment. It is a handsome variety; the pitchers are rather short and broad, averaging from three to four inches in length, light green in ground color, profusely spotted and blotched with dull red. *N. Hookeriana* is also a well-known species of vigorous growth and handsome form; the leaves are broad, dark green and slightly pubescent; the pitchers are formed at the end of long stalks, and are dark green with reddish markings. Like those of the preceding variety, they have two broad wings with ciliated edges down the front of the pitchers.

Hybrids having pitchers of the broad form are largely derived from *N. Hookeriana* or from *N. Rafflesiana*.

N. Rafflesiana is decidedly one of the finest species in the whole genus. It is a strong grower, and produces immense pitchers, which are sometimes ten to twelve inches in length. The pitchers of *N. Rafflesiana* are dark green, with chocolate markings, and they also have two broad wings down the front. Like most of the members of this genus, the pitchers of *N. Rafflesiana* are subject to variations in shape; the most notable usually precedes the period of flowering, when the pitchers become much elongated and have less color than when in their best condition. In order to prevent this deterioration in form it is advisable to cut back the plants occasionally, and thus induce a short-jointed new growth from the bottom.

N. Morganianæ is another remarkably fine hybrid, and was one of those originated in the first lot of hybrids raised in this country. It is of moderate growth, the leaves pale green, with reddish midribs, and the pitchers flask-shaped and almost entirely blood-red when in perfect condition. *N. Sedeni* is also a fine hybrid, and was raised in England a number of years ago. In habit and shape of the pitchers it resembles *N. distillatoria*, but the pitchers of *N. Sedeni* are much marked with brownish crimson. Among the smaller-growing species *N. phyllamphora* may be recommended; it is of free growth, and produces its bright green pitchers in great profusion. *N. rubra* is of somewhat similar habit, but the pitchers are flushed with dull red.

Other fine species and varieties are *N. Dominiana*, *N. ampullaria vittata*, *N. hybrida maculata*, *N. sanguinea*, *N. Rajah* and *N. lanata*. The last three are somewhat rare, and *N. Rajah* is also notable from the fact that its pitchers are the largest of any species in cultivation. In conclusion it should be remembered that the *Nepenthes* grow naturally in swampy ground, and therefore should never be permitted to become very dry, while during bright dry weather in summer frequent and copious syringings will be found beneficial to them.

Fig. 25.—Seedling Egg-plants destroyed by a Fungus.

"Falling" of Egg-plant Seedlings.

THE growers of Egg-plants are much troubled with what they call "falling," and unless they exercise great care all their plants may die before passing beyond the seed-leaf stage. In a recent visit to several large growers of Egg-plants I observed that the seedling-beds were frequently spotted—that is, had patches usually circular, and varying from a few inches to two feet in diameter, where the seedlings were dead, while all around the border new victims were falling. This indicates that the trouble originates at certain points, and from there spreads in all directions. These seedlings, when carefully removed soon after becoming prostrate and washed of the earth at the roots, show that the stem is nearly eaten away at the

surface of the soil and the root-system is likewise destroyed. Several plants thus killed are shown in the illustration. The picture was secured by first cleaning the seedlings and afterward floating them in water upon a white plate. By means of a vertical camera the photograph was then taken from which the plate has been made.

The cause of this "falling" of the seedlings is a fungus which is quite common to the seed-bed of gardeners, and about which much has been written from year to year. This fungus, a species of *Pythium*, and probably *P. De Baryanum*, infests the soil of the propagating-bed and thrives upon the substances it contains. Like many other kinds of fungi, it attacks its tender victim near the surface of the soil, and quickly destroys the soft tissue, after which the seedling topples over and is gone. The fungus may cause the fallen top to decay rapidly, while other filaments reach out to new victims not far away.

A remedy for this serious pest, it is hoped, may be found during the present experimentation. The strong heat and abundant moisture that are essential to the development of the Egg-plant seed are the appropriate conditions for the growth of the fungus. Some soil-treatment needs to be found that will first destroy all the *Pythium* germs, then by continuing with a fungicide it is hoped that control may be obtained over this enemy. One of the substances now being tested is corrosive sublimate (bichloride of mercury), and the point to be demonstrated is whether this can be profitably employed. The chief objection to this germicide is its poisonous action upon the human system, and must therefore be used with extreme caution.

Correspondence.

Southern Forests and Forest-flowers.

To the Editor of GARDEN AND FOREST:

Sir,—American wild-flower clubs in different localities are doing some good work, but all the useful, rare and beautiful species cannot be grown in gardens half as successfully and plentifully as nature grows them in their forest-homes. Since for "health and for wealth" to this great American nation forests must be left standing, why not try to preserve them intact—trees, flowers and all? Before cultivation, travel and free mountain-pasturage many beautiful wild flowers are disappearing. Those plants whose medicinal qualities are well known find in the herbalist a serious foe. It is not the land-owner, but a shiftless population, who reap this wild harvest, and send yearly to the great herbarium at Statesville, North Carolina, thousands of pounds of dried herbs and roots. Here among the mountains of western North Carolina, so rich in medicinal herbs, farmers leave their fields half-cultivated and growing up with weeds to gather elsewhere a harvest which is rent free. The large southern land-owner is too careless of his interests. His acres of uncultivated land, full of game of all kinds, fruits and berries, and the finest of timber, are really the common property of a thriftless population. Even rich beds of surface mineral they plunder lawlessly, and should they be forbidden free pillage by the owner they revenge themselves by damaging him in every way possible. This may sound like a sensational tale, but it is true. The slack system which prevails here is ruinous to the whole population, and nature is robbed unsparingly of her wealth and beauty.

Two yearly forest-fires are set, "by accident," or "nobody knows how"—one in autumn, that these semi-civilized creatures may more easily gather the nut-crop hidden beneath fallen leaves; and one in spring, that their flocks may have better pasturage. Both are disastrous to fauna and flora and fencing for a forest-fire is not easily controlled. There are protective laws for some wild plants—Ginseng, for instance. Once our mountains were full of this valuable plant, but every year it is becoming scarcer, and all because collectors will gather it before the seeds are fully matured, notwithstanding the law in this state prohibiting the collection of Ginseng before September. The roots sell at \$3.25 per pound in Statesville, North Carolina, and hundreds of pounds are shipped there by local dealers from this section, but not a dollar of it goes into the land-owner's pocket, nor can he, without keeping a strict watch upon his hundreds of forest-acres, save the plant from extinction. To prevent this it is now being successfully cultivated in the edges of forests partially cleared.

Another medicinal plant of rare beauty is the Gentician (*Gentiana crinita*). Its root is a powerful bitter tonic, a recognized cure for headache and dyspepsia, and often used as a substitute for quinine; therefore it brings a good price and is in great de-

mand by herb-dealers. The name is such a familiar one that the plant is commonly supposed to be plentiful in woods and meadows, but such is not the case in this region. I remember that when a child I used to think the Fringed Gentian only a fabulous flower, and now it is quite a find in our woodlands, but it is of such rare beauty, so distinct in the depth of its blue, that it is the object of constant pursuit.

The closed Gentian—*G. Andrewsii*—are much more common than *G. crinita*. The flowers are thickly clustered at the tops of the stems, pink or blue in color, and always closed. Found usually in damp, open woods along streams they are quite pretty. A beautiful second to *G. crinita* is *G. puberula*. Its indigo-blue flowers, nearly the shape and size of a Canterbury-bell, are borne in a cluster at the top of the plant, and last a month or more during September or October. Three members of the Gentian family are catalogued by florists. *G. quinqueflora*, or the five-flowered Gentian, sometimes called Gall-weed from the exceeding bitterness of its juices, has slender, branching stems two or three feet high, with rather small, pale blue or light purple flowers. *G. cristata* is much like *G. crinita*, with the exception of being larger. The flowers are bright blue in color, and beautifully fringed, nearly two inches long, opening only in sunshine. It is found wild on wet swampy lands, and makes a good edging for artificial lakes and ponds. *G. serrata* is the Smaller Fringed Gentian, having smaller flowers and narrower leaves than the two already mentioned; these leaves turn bright crimson with the breath of autumn.

These species, though safe from extinction, will doubtless be dwarfed and doubled and crossed and recrossed till little of their original beauty remains. Under cultivation, Gentians like a light rich soil, partial shade, and free circulation of air. The biennial varieties are increased by dividing their roots, and the annual ones by seeds, which should be sown as soon as ripe in autumn. Nearly all the Gentians are blue in color, and flower in September or October.

Even if the wild-flower club should succeed in gathering and cultivating all valuable wild plants, how bare our forests would be without them! The Gentian and Ginseng families are only two out of many which appeal to us. Every land-owner ought so to regulate his little kingdom that it may yearly increase in beauty and value. We need more laws protecting plants and forests, else the deserted farms of New England will be duplicated in many now fertile regions of the south.

Garden City, N. C.

L. Greenlee.

Grafting.—II.

To the Editor of GARDEN AND FOREST:

Sir,—No doubt, top-grafting devitalizes a tree or ruins the limb operated on when the work is improperly done. Sometimes a limb two inches in diameter, or even more, is sawed off; a cleft is made in it; two grafts are inserted opposite to each other, and the wound is carelessly plastered with softened grafting-wax. Such attempts are likely to fail for various reasons. In the stump of a limb of the diameter above named there should be at least four grafts placed, at opposite extremities of two clefts made at right angles to each other. The object in placing so many grafts is to maintain sap circulation on all sides of the amputated limb. Thus, for example, if in a limb two inches in diameter a graft be set in one side only the side opposite the graft will be very certain to die, the wood will then decay, and that piece of grafting (even if the one graft grows) will ultimately prove a failure. Hence, in grafting stumps of such diameter the work after being done should be in a few days inspected, and if any of the grafts show sign of failure others should be at once put in their places. In a year or two the surplus grafts may be cut out, and the wound will gradually and completely heal if life is retained all through the limb which was treated. In limbs of larger diameter than two inches it is safest to "crown-graft," which method permits the setting of as many grafts as may be needed to maintain circulation.

To show some horticultural friends that it could be done successfully, I some years ago sawed off the trunk of a Sheldon Pear-tree below its branches, where its diameter was four and a half inches. Around its circumference I set sixteen crown-grafts. This tree will make a new head, and will bear a good many pears this year. This is an extreme case, and was done more for experiment than with a view to useful results. Another tree in my Pear-orchard, a Lawrence, was attacked years ago by fire-blight. I sawed it off at the ground (the stump there being six inches diameter) and crown-grafted the stump. Two of the grafts I have left growing, and they

are now twelve feet in height, and last year bore a full crop of Kieffer pears. In a year or two I shall remove one of these grafts, probably regrafting its stump, simply to maintain circulation, and ultimately there will be an entire new head on a root twenty years planted.

The most important point in the surgery of top-grafting is the waxing of the wounds made in stock and graft. Every "solution of continuity," as the surgeons express it, should be sealed tightly. This may be most surely effected by using liquid wax, made of resin, linseed-oil and beeswax, tempered so as to be when cold solid, but yet elastic, not flinty, and for use warmed until liquid in a portable furnace and applied to all the cut parts of stock and graft with a small paint-brush. Then all the grafting-work should be gone over, and, next day, where needed the joints should be rewaxed. I have never yet done my work so thoroughly that I found no faults to remedy afterward.

Vineland, N. J.

A. W. Pearson.

In the Gardens of Brookline, Massachusetts.

To the Editor of GARDEN AND FOREST:

Sir,—The greenhouses in this locality are always interesting, and the noble Palm-house of Mr. Joseph H. White is in itself well worth a visit at any time of the year. There are many Palms and Tree Ferns of magnificent proportions at this place, and the healthy appearance of the plants shows rare skill in their management. Two gigantic specimens of *Monstera deliciosa* cover a large portion of the walls of this house with their rich green and boldly effective foliage, and it has been necessary to "top" and otherwise prune a handsome plant of *Araucaria excelsa*, as it had become too large for the lofty edifice. This operation was performed two years ago, and the number and vigor of the lateral shoots prove that the tree has not seriously suffered from it. A fine display of bloom was found in the Rose-house, and the gardener, Mr. Wheeler, speaks with enthusiasm of the Waban, of which he grows many plants. Worth special mention among the plants in the other houses were Carnations, Easter Lilies, *Spiræas* and *Cytisus*, large quantities of which are grown for cut flowers. Several large bushes of the *Laurestinus* (*Viburnum Tinus*) are grown for the same purpose, as the flowers are found extremely useful in the spring. The Peach-trees and Grapevines, in the cultivation of which under glass Mr. Wheeler is quite a specialist, are now in prime order.

At Mr. John L. Gardiner's, where Mr. Atkinson presides, there is a rich assortment of useful plants. *Bignonia venusta*, rambling freely about the roof of a large house, is a brilliant mass of orange-colored flowers. A small plant of *Kennedyia monophylla*, loosely trained to stakes, bore enormous quantities of its pretty little blue blossoms, and a tall specimen of *Ardisia crenulata*, with its profusion of bright scarlet berries and deep green foliage, showed the remarkable utility of this much-neglected plant. Mr. Atkinson assured me it had been quite as good ever since Christmas, and its beauty shows no sign of waning. Great numbers of spring-flowering bulbous plants are grown here in pots, including, besides ordinary kinds, many odd varieties of *Narcissus*, and they are exceptionally well grown. *Veltheimia viridifolia*, a rather uncommon Cape bulbous-rooted plant, with bright green leaves and densely flowered erect scapes, the flowers being tubular and of a pale rose-color, is well represented. Two pans of the double white *Primula Sinensis* formed charming pictures, the pale green of the leaves contrasting well with the flowers. This is a most useful plant, and it is all too scarce in the gardens of the United States. The market-gardeners of London grow it by the thousand, and it always commands a ready sale. The flowers last much longer than those of the single varieties, and they are most useful for cutting. The exquisite odor of its neat little chocolate-colored flowers betrayed the presence of *Boronia megastigma* in nearly every house. Mr. Atkinson finds young specimens of this plant from two to three years old the most serviceable. It is propagated from cuttings, and during the summer months, if planted in the open garden, it makes vigorous growth, which insures abundant bloom, before it is taken up for potting early in autumn. The odor from a single healthy flowering specimen in a six-inch pot will scent a large room or greenhouse. Many more old-fashioned garden-plants are to be found in the collection here, and they have a great charm as old acquaintances when seen as a gardener of long experience knows how to grow them.

Orchids are an important feature, too, and many excellent specimens are seen. The *Calanthes* have passed their flowering stage, but the well-developed pseudo-bulbs are sufficient evidence of what the blooms had been a few weeks earlier.

The best plant of *C. Veitchii* produced a spike which bore forty-seven flowers, and the others were proportionately good. Many grand plants of the stately *Phajus grandifolius* are in full bloom, and one of *Cattleya Trianae* can hardly be excelled. The numerous plants of *Laelia harpophylla*, with their bright orange-scarlet flowers, have a cheerful effect amid the prevailing green, while the fragrant drooping racemes of *Dendrochilum glumaceum* and *D. Cobbianum* give a final touch of grace and elegance to the scene.

Cinerarias and Cyclamens are the principal attractions at Dr. C. G. Weld's place, one large house being filled to overflowing with splendid specimens of these plants. The seeds of Cineraria were obtained from plants of Raymond's California strain. The flowers are of good size, and rich in variety and shade of color. There are some handsome double varieties among them, which may possess decided merit for cutting purposes, but they are not nearly as attractive as the single kinds. To obtain these fine plants the gardener, Mr. Kenneth Finlayson, sows the seeds early in summer, keeping the plants as cool as possible and shaded throughout the hottest months. A mixture of rich loam and leaf-mold, in equal parts, with a moderate addition of sand, is used for potting when the plants are young, and as they require larger pots the compost is gradually made stronger and richer by adding old cow-manure and more loam. Liquid-manure is given once or twice a week when the final pots are filled with roots. Several of Dr. Weld's houses are devoted to Roses, and there is one full of Carnations in pots. Among the latter, Annie Webb, Florence, Lizzie McGowan and Silver Spray were considered reliable. The bareness of the bench-walls in the Rose-houses was relieved by large hanging tufts of *Abutilon vexillarium*, and numerous pots of *Oxalis lutea*, full of its large canary-yellow flowers, hung from the roof. The clear scarlet flowers of *Anemone fulgens* are very showy and conspicuous, and the plants are blooming freely and seemed to thrive well in pans of moderate depth. *Iberis sempervirens* is a perfectly hardy plant, but it is used here for forcing in pots. The specimens are dwarf and compact, and covered with the pure white flowers. A recently imported piece of the famous *Cattleya labiata* bears a single flower, large, beautiful and fragrant, with sepals and petals soft purple, lip white with conspicuous markings of deep purple. *Trichopilia laxa* is also in bloom, and is interesting on account of its comparative rarity. The racemes are of drooping habit, the flowers odorous and pure white, the broad lip yellow at the base.

Cambridge, Mass.

M. Barker.

Wild Flowers in Cultivation.

To the Editor of GARDEN AND FOREST:

Sir,—Every student of nature must have observed the changes made in our native plants by domestication. A simple change in environment is sometimes sufficient to make a radical change in the habits of growth and flowering of such plants. One of the showiest wild flowers of southern Missouri is *Verbena Aubletia*. In its wild state it commences to bloom very early in the spring, and for nearly two months is a mass of reddish purple blossoms, so bright as to catch the eye at a long distance. After the regular spring flowering is over, however, one rarely sees a wild plant in flower, and at the most but a few spikes at a time. Wild plants transplanted to the home grounds immediately make an astonishing growth, each plant reaching two or three times the size of its wild companions, and remaining constantly in flower from early spring until October. In ten years' experience with them I have found this an invariable rule. I give my plants no cultivation further than to plant in mellow soil and to keep free from weeds. The flowers in size and color remain true to the type, the change being solely in increased luxuriance and continuity of bloom. Can any one suggest the reason for this change of blooming period or how it is brought about?

Even more striking is the change in *Viola pedata*, the beautiful Bird's-foot Violet, whose natural time and duration of blooming is about the same as that of *Verbena Aubletia*. I have transplanted Bird's-foot Violets by the hundred, giving them such after-culture as I give ordinary flowers. The blossoms of cultivated plants are no larger than those on wild plants, perhaps not quite as large, but during their regular blooming period they are borne in remarkable abundance, and give irregular but less profuse crops the whole season thereafter. My last summer's garden notes show that there was not a day between the middle of April and first of November when I could not find plants of this Violet in bloom.

In one bed I have several plants of the rarer *Viola pedata* bicolor, the three lower petals of which are a satiny blue, while

the two upper ones seem stamped out of royal purple velvet. This spring half a dozen plants gave blossoms whose lower petals were dotted, splashed or striped with the purple of the upper petals. Sometimes the variegation was slight, but every bloom throughout the season showed it. The season before a bed of choice Pansies grew near the Violets. Was this a case of accidental hybridizing? It seems almost incredible that cultivation alone should cause such sporting, for the wild ones are always true to type.

Pineville, Mo.

Lora S. La Mance.

Exhibitions.

The Spring Flower Show at Philadelphia.

THE exhibition of the Pennsylvania Horticultural Society last week was more successful in point of attendance than any spring flower-show in Philadelphia for many years. There was no staging in the large hall and all the plants were tastefully grouped on the floor, giving the general effect of a well-arranged garden. The great private collections in the city and its neighborhood, as usual, contributed liberally from their treasures, and the show was rich with choice specimens from the greenhouses of Miss Baldwin, Mr. Drexel and Mr. Childs. Two plants from Mr. Childs' collection, well known for their size and beauty, a superb *Livistonia* and a *Cibotium regale*, of truly regal proportions and expression, were seen for the last time here, as they have been contributed by Mr. Childs to the Horticultural Department of the Chicago Exposition.

A group of Palms and other decorative plants from Mr. Drexel was remarkable for high average value of its individual specimens and their admirable condition. Mr. Thomas Long, the gardener who cares for these select specimens, received the first premium for a new and rare plant with a variety of *Araucaria excelsa glauca*, which was quite distinct from the type in its larger and broader leaves and more robust habit. The group of twelve Ferns, also sent by Mr. Drexel, it would be difficult to match for size and perfection of form. It contained *Davallias*, *Gleichenias*, *Cibotiums*, the variety *Major* of *Pteris serrulata cristata*, the crested *Microlepia hirta*, *Nephrolepis davallioides*, and an exceptionally good plant of *Adiantum Williamsi*. Wm. Joyce, gardener to Miss Baldwin, also received prizes for Palms and decorative plants which added much to the general effect of the exhibition. John M. Hughes, gardener to Mr. Childs, received special premiums for the same classes of plants. The Girard College gardens seemed to be the most liberal contributor. Palms, Tree Ferns, Crotons, *Dracænas*, with *Azaleas*, *Cytisus*, *Deutzias* and other hardy shrubs forced into bloom, Pitcher plants and spring flowers in variety were banked against the stage most effectively, and Mr. George Huster, superintendent of these gardens, well deserved the silver medal awarded to him for taste in arrangement as well as the special premium for his plants.

As this was a spring show, the lack of bulbous plants in flower was noticeable. Of Bermuda Lilies, usually so abundant, there were very few; of *Lilium longiflorum* none. All the Tulips, Hyacinths and Narcissi would have been lost in a collection of ordinary size, and of the rarer Daffodils in which amateurs take such a lively interest, only a few of the varieties were represented. This was unfortunate, for certainly this class of plants is worth growing and showing, and a spring flower show is the place where they ought to be seen.

In the foyer the Carnations attracted most attention, the point of special interest being the competition for the Craig Cup for the best twelve blooms of a variety not disseminated. Among the leading competitors for this was E. G. Hill, of Richmond, Indiana, with *Edna Craig*, a very light pink, now the most fashionable color. The flower is very large, with a stiff stem, a perfect form, and a calyx which never splits. Edwin Lonsdale, in the same class, showed *Grace Battles*, a pink flower of a shade deeper than that of *Edna Craig*, and a first-class flower in every way. J. W. Colflesh exhibited another pink flower, Mrs. Colflesh, still deeper in color than *Grace Battles*—that is, about the color of *Grace Wilder* at its best. These flowers are larger and bolder than *Grace Wilder*, and shown on stems eighteen inches long they were very striking. Sentinel was called a crimson-scarlet, which means that it is about the same color as *Hector*, with a good stem and calyx. These four varieties were most notable as showing in a marked way the recent advance in Carnations. There is still room for a new dark crimson which will be as great an improvement on *King of Crimsons* as the new pink kinds are beyond the old ones. A good yellow is still needed. *Golden Gate* bursts badly; sometimes into utter raggedness. Of the better-known varieties, Lizzie McGowan showed very well even alongside

of some admirable Lamborns. Wm. F. Dreer, a rosy pink, one of last year's novelties, showed especially well under gas-light. It is of perfect form and a first-rate variety. The cup was won by Mr. Hill, and special mention was made of Mr. Colflesh's entry. Premiums for cut Carnations were awarded to C. J. Pennock, H. E. Chitty, Wm. Swayne, John Crawford, Joseph Heacock, J. J. Styer and Pennock Brothers.

The display of Orchids was not large, but it was good, and Edwin Lonsdale received the first prize for twenty-five well-grown varieties in bloom with good healthy leaves, and showing admirable culture. Messrs. Siebrecht & Wadley also had a good exhibition. Messrs. Pitcher & Manda had something like two hundred small vases containing cut Orchid-flowers of the most beautiful varieties. They were arranged on staging built in a circular form around an immense Kentia from Miss Baldwin's collection. Among the flowers were those of *Cypripedium Amesianum*, *C. luridum*, *C. Shroederæ*, *C. pavoninum inversum*, the variety *Josephine* of *Odontoglossum crispum*, *O. triumphans aureum*, *O. sceptrum*, and the white forms of *Lycaste Skinneri* and *Cattleya Trianae*. Besides the Orchids, this group contained many of the new and rare varieties of *Anthurium*. Cut Roses, both Teas and hybrids, were exhibited in quantity, and blooms of Baroness Rothschild, Ulrich Brunner, Catherine Mermet, La France and Madame De Watteville were especially good. Bridesmaid, the new sport from Catherine Mermet, appeared in very good form. It is a darker pink than the type, but not so dark as Waban, and the growers consider it a variety of much promise. Other prominent features were the Azaleas of James Dean, W. K. Harris and David Emory, gardener to Charles Dissel; the French Cannas, for which Mr. H. A. Dreer received a certificate of merit, and Mr. Blanc's Cacti, of which there were probably two hundred on the stage, many of them showing beautiful or grotesque flowers. On the last afternoon of the exhibition visitors were presented with small Cactus-plants from Mr. Blanc, all neatly packed and ready for planting.

The special prizes offered for twenty-four specimens of Mushrooms brought out a strong competition in this class. The first prize was won by David Allen, of Boston, and the second by N. P. McCaffery, of Moorestown, New Jersey.

Recent Publications.

Nature in Ornament. By Lewis F. Day. With 123 Plates and 192 Illustrations in the Text. London, B. T. Batsford; New York, Charles Scribner's Sons. 1892.

Mr. Day's seems to us the best book yet published on this interesting subject, and its usefulness will be increased by the fact that it is small and not expensive. It is equally valuable as an historical account of the aims and methods of those who have in the past designed ornamentation based upon natural forms, and as a guide to those engaged in the same work to-day. It will be found interesting by mere lovers of art, and instructive to all designers, from those whose work is architecture to those who spend their leisure hours embroidering. If original designing is contemplated, Mr. Day's words and illustrations will put the student upon the right road. And if patterns to copy are desired, he offers a very rich and varied treasury. The scale of his pictures is so small that it may not often be found possible to trace them off for repetition. But they are strongly drawn and clearly printed, and they can easily be copied by persons who have had any practice in free-hand drawing or in mechanical processes of enlargement.

As the table of contents shows, Mr. Day speaks first of "Ornament in Nature," and then of "Nature in Ornament"; then of the simplification of natural forms and of their elaboration; of "Consistency in the Modification of Nature," of "Parallel Renderings," of "Tradition in Design," of "Treatment" (from the more technical point of view), of "Animals in Ornament" and the "Element of the Grotesque," of "Still Life in Ornament," and, finally, of "Symbolic Ornament." There are few sentences in any of his chapters which are not explained by reference to some pattern which he reproduces; and his reproductions have been drawn from every kind of work, from architectural carvings to silken fabrics and Oriental carpets, and include, moreover, many simple renderings of natural vegetable forms, which greatly enhance the significance of the conventionalized forms that have been derived from them.

It is hard to pick out any chapters for especial commendation where all are good, and, of course, the value of one largely depends upon its relation to the others. But the chapters on "Parallel Renderings" will perhaps be found the most interesting by the average reader. Here Mr. Day says, that

while the "partiality of each particular period and country for a certain few, usually symbolic types, makes it impossible to trace any one single natural form through all history," yet most forms can be traced "through a variety of historical developments," and that "the type of most universal occurrence is probably the Vine, a symbol of philosophies as wide apart as the poles." And then, beginning with the bas-reliefs of Nineveh, he describes and illustrates the ornamental treatment of the Vine among men of every race and in products of every artistic kind, following up this account with briefer but equally interesting ones explaining the artistic history of the Rose, the Pink, the Poppy, and so on. Moreover, at the beginning of this chapter we find so excellent a summary of what the student's attitude toward Nature should be that we cannot refrain from quoting it somewhat at length:

"The study of ornament should proceed, I think, *pari passu* with the study of vegetable forms—not botany necessarily. The scientific study of botany is quite a thing apart. The ornamentist has no more occasion for exact scientific knowledge than the painter has to know surgically about anatomy. We want, in either case, just science enough to enable us to see the surface of things. The classification of a plant according to its hidden organs is as nothing to us compared with its character, its beauty, the hint in it of ornament. An artist can do with comparatively little science if only he make full use of his eyes. Suppose the student in ornamental design to have begun by being well grounded in practical geometry; soon he might proceed to put together, somewhat on the kindergarten system, geometric patterns. . . . Then, as he grew beyond this elementary stage, he might exercise himself in drawing freer and more flowing forms, say, until he acquired the facility in sketching off (with the brush) ornament of the kind the Greek pot-painters drew with such freedom. Simultaneously with this he should be making intelligent studies of leaves, flowers, fruits, and all manner of details of plant-form and plant-growth. With equal diligence he should be studying the masterpieces of applied design, especially noting the way the masters treated those same natural forms, and always choosing his model, whether of plant-form or of ornament, for the definite reason that it meant something to him. His studies should be carried just so far as their purpose warranted; there should be no attempt to make pictures of them, or show-drawings, or to make them even presentable. What the student has to do is to make notes serviceable to himself, sufficient in every case to impress upon his memory what the original conveyed to him, records of what he wanted to record. The urgent need of choosing each example needs the more to be insisted upon, because the designer cannot too early begin to cultivate the selective faculty. Judgment is one-half the battle in decoration. The closer the relation between a man's studies from nature and his studies from old work the better. Take, for instance, any flower you like and study it from nature carefully—its form, its structure, its growth, its color, its character; then see how it is rendered in Classic art, in Gothic, in Renaissance, in Japanese, in Persian, and so on. Observe, again, its treatment in sculpture, in inlay, in metal-work, in textile fabrics, and what not. A series of such exercises, conscientiously and thoroughly done, would be an education in itself, and would in some degree fit one to conventionalize on his own account."

The extract is significant as revealing the broad-minded spirit in which the book is written. Many previous writers on the subject have been, either too strongly archæological or naturalistic in their sympathies; but Mr. Day recognizes with equal sympathy the rôle of nature and the rôle of ancient art as teachers. Nor has he any unfortunate prejudice for or against any special phases of art; everything that is good appeals to him, while he can see mistakes even in the work of the most famous of the ancients. He excludes no kind of good work, and, on the other hand, he sets up no fetishes. Much as he loves nature, he carefully explains how natural forms must be altered for purposes of decoration; and much as he loves art, he cannot praise even very attractive work if it sins against fundamental natural truths.

As this is not a journal devoted to the arts of design, except as the landscape-gardener is concerned with them, we should not give so much space to Mr. Day's excellent book but for the fact that there is an obverse side to its usefulness. If it can teach the artist how to appreciate and use nature, it can also teach the lover of nature how to criticise and appreciate ornamental art; and such knowledge, if widely spread, will advance the cause of art as greatly as improvement in the artist himself.

Moreover, the perusal of Mr. Day's book will profit lovers of nature simply by increasing their appreciation for natural forms themselves. Every one knows how vastly his interest

and pleasure in a particular kind of natural scenery is augmented if he is familiar with the work of some great landscape-painter who has interpreted that special kind. We do not now refer to the actual portraiture of special scenes and sites, but simply to that preference for one kind of landscape-beauty which most landscape-painters exhibit. It does not matter whether or no we ever look upon the actual scenes that Corot portrayed, or even whether he ever exactly portrayed any given spot. He illustrated and poetized a special type of landscape, and when we see this type in France, or even along our American stream-courses, we understand it better because we have seen it upon his canvas; and especially if the hour is morning and the time is spring—the hour and the time when Corot best loved to paint. It is the same with Rousseau and the great masses of brown-red foliage which he loved to depict, and with Diaz and his dusky green woodland glades; and the same with Ruysdael and the wide gray sandy stretches of Holland, and with Cuypp and his fertile valleys, herds of placid cattle and golden sunlight. And as it is with these painters of landscape, so it is with the designers of ornament. If we know their work, we see more in the natural forms they adapted than we ever did before, and appreciate them more thoroughly. Mr. Day's book, therefore, should recommend itself strongly to the readers of GARDEN AND FOREST, even though they may have no practical personal concern with the art it explains.

Notes.

The last line of the article on Chrysanthemum Blight, which appeared in our last issue (page 153), should read "one gill" instead of "one pint." Professor Beach writes that his attention was directed to the error by Mr. John N. May, of Summit, New Jersey. The correction is important, since a solution as strong as that originally given would probably injure the plants.

We have received from Rea Brothers, Norwood, Massachusetts, flowers of *Primula Sieboldi* and half a dozen varieties sufficiently distinct to be worthy of separate names. These flowers, which came in excellent condition, were grown in a cold frame, but they are perfectly hardy in sheltered situations, and they make a good addition to the flowers which bloom in April and May.

Last week a public meeting was held in Vineland, New Jersey, at which the fruit-growers of that region met with the merchants of Brooklyn, New York, Philadelphia, Trenton, Paterson and other cities to discuss the practicability of sending berries to market in packages which were not returnable. A good deal of money is now invested in these packages, so that this change cannot be made at once, but it looks as if the current of business sentiment is in that direction, and that the reform will come in a year or two.

Mr. John Thorpe is reported in the *American Florist* as having recently said that the project of an International Chrysanthemum Show was under consideration by a committee of the Local Directory of the World's Fair. A technical objection had been raised on account of a clause in the charter which might be construed so as to prevent the taking of an admission fee for entrance to the ground before the opening of the fair, but he believed that this point could be adjusted and that the exhibition would be held and be worthy of the great occasion.

Complaint is often made of Foxgloves and some other herbaceous plants which are sometimes sold as perennials, that they die away after flowering and are really biennial plants. *Meehans' Monthly* calls attention to the fact that they can be made true perennials if they are prevented from going to seed. It is the production of seed which exhausts the vital powers of the plant. If the stalks of Foxgloves and other plants are only cut off as soon as the flowers fade and before the seeds are formed, there will be no difficulty in having them live for a number of years. Those who wish to increase perennial plants rapidly do not let them flower at all. Where seed is needed, one or more plants can be allowed to produce and ripen it.

The question of our common roads has become of such general interest that it is no surprise to find it made the subject of the leading article in *The Century* magazine for this month. The letter-press of this article is good, but it is the illustrations which make it particularly valuable. No one can see the pictures of wheels blocked and horses and human beings struggling through mud knee-deep without being reminded of what is going on over a large portion of the northern states at this very hour. The waste of temper, vital

energy and time due every year to the bad roads of the United States, when taken in the aggregate, is a tax which nothing but a young and prosperous country could endure. No one can look at these pictures without feeling that delay in mending our ways is little less than criminal.

Much sound advice is condensed into a paragraph in the last *Country Gentleman*, which is written for farmers who seem to feel that a great deal of ground is needed for a fruit-garden, when in reality a small lot reserved for this purpose and properly cared for will yield much more than the ordinary home garden affords. Here is the advice: "Set off a piece of ground three rods wide and seven rods long, or a little more than one-twentieth of an acre. Lay it out in straight lines running lengthwise, so that all may be cultivated with a horse, and leave a space ten feet wide at each end for the horse to turn on; then plant three rows with Strawberries, one with Fay's Currants, one with Raspberries, one with Dwarf Pears and the rest with Grapes. With horse cultivation one hour's labor a week will keep the ground clean and mellow and will give a delicious supply of fresh fruit through the greater part of the season."

According to the act for establishing a botanical garden in this city, which was passed about a year ago, it was made necessary that \$250,000 should be raised by the incorporators before they could secure \$500,000 in bonds from the city and the use of the 250 acres in Bronx Park. Mr. J. Pierrepont Morgan and four associates were therefore entrusted with the task of soliciting subscriptions, and Mr. Morgan's plan was to obtain ten subscriptions of \$25,000 each. It is stated in the daily papers that he has already secured eight of these, and there will probably be no difficulty in raising the whole amount. Those who know what an establishment of this kind will cost will be pleased to learn that the subscription is not to stop here, but that many other persons who have expressed a willingness to pay \$10,000 and smaller sums will be permitted to contribute, so as to raise at least \$250,000 more, making a clean million dollars to begin with.

It is incorrect, according to the recent authority on the subject, to speak of the Chrysanthemum as the national flower of Japan, which rank really belongs to the Cherry-blossom. The mistake is probably owing to the fact that the Chrysanthemum is used as one of the crests of the imperial house, and has been highly honored by the court since at least as early as the ninth century, when garden parties were held in the palace for the purpose of celebrating its blossoming time, as in modern days yearly Chrysanthemum shows are held in the imperial gardens. "The ancient celebrations," says the writer from whom we quote, "seem to have partaken of a truly pastoral character, the courtiers wearing the plucked blossoms in their hair, drinking wine and composing verses upon the beauties of the flowers. The modern Chrysanthemum displays in the palace gardens are more like our own flower-shows in the social conventionality of their arrangement; but the numerous variety of every imaginable color and profusion of shape, arranged in long, open, rustic sheds, forms a brilliant and imposing scene hardly rivaled by any flower-show in the world."

In the last annual report of the Botanical Gardens at Georgetown, Demerara, it is said that bananas hold a very inferior place in the domestic economy and estimation of the general public as compared with plantains. They are not, as plantains are, regarded as an essential article of food, nor are they particularly sought for by the working classes when they come in their way. The preference of the inhabitants of temperate countries for the banana as against the plantain is due to the fact that as it is consumed raw, only a moment is required to become acquainted with and appreciate its merits. On the other hand, a long time and steady acquaintance is required before the plantain is properly appreciated. The most abundant bananas in the markets of Georgetown are the Dwarf or Chinese kind, and next to that the large and small Fig bananas. The large Indian banana differs from all others in its size, wide angles and softer texture, and is the best of all for cooking purposes, although, as has been said, bananas are almost exclusively used raw. They may, however, be preserved with sugar in various forms, or turned into jam or dried and packed like figs. These methods of preservation have all been tried on a small scale in various parts of the West Indies, but mostly in an amateur way. But no one seems to have thought it worth while to make the necessary outlay of money and time in order to place this fruit cheaply in the markets of temperate countries as other preserved fruits are. Samples never make a market for any commodity. Cheap and abundant supply is necessary to create a permanent demand.

Arbor Day.

DURING the past month we have received several reminders of the approach of Arbor Day in the way of circulars and pamphlets suggesting proper exercises for the ceremonial observance of that festival. They are generally issued by the State Superintendents of Public Schools, and contain a good deal of music and poetry, with selections in prose and verse suitable for recitation. Every effort to make this celebration an attractive one is praiseworthy, but in addition to the songs and orations we should like to see in these programmes greater effort to instruct the young people in some of the advantages and uses of trees, some of the fundamental facts relating to their growth and structure, and particularly some explicit directions as to planting them and caring for them afterward. Arbor Day is intended to encourage tree-planting. Its highest use is only reached when children, and their parents, too, are moved to plant the best trees in the best way. It requires no great amount of intelligence to thrust the roots of a tree into a hole in the ground; but to plant a tree as it should be planted—that is, to plant it so that it is likely to attain its best possible development and reach a green old age—is a work that requires care and skill. There are few things which men do where the difference between careless work and good work will show so plainly, or for so long a time, as in the planting of a tree. In the first place, the site for planting should be intelligently chosen, then the variety suited to the peculiar soil and situation and use for which it is intended should be considered. A good specimen of this particular tree should be selected and the ground should be thoroughly prepared to receive it. Even then, after the soil is properly firmed about its roots, the tree should not be neglected and suffered to fall a prey to insects or fungi, or allowed to starve for lack of food or water, or to be loosened by the wind.

One of the most instructive exercises of Arbor Day in

every district where the day was celebrated last year, or in the years before, would be an examination by the children of the trees which had previously been set out, to see what proportion of them were thrifty and had made as good a growth as could have been expected. Professor Beal once related a very instructive incident in these pages. A few years ago each class and society of the Michigan Agricultural College planted a memorial tree with some ceremony. These trees were publicly accepted by the President, and the care of them was guaranteed. A year later reports were made which proved how much easier it is to plant a tree than it is to give it proper care afterward. Of the twelve trees not one had made satisfactory growth, none had been mulched, only one had received any cultivation, one was dead, two nearly dead, one had been cut down, and nearly all the rest of them were having a severe struggle with thin soil, grass, weeds, lack of moisture and insects and fungi.

It is a beautiful custom—this planting of memorial trees—but in order to make it impressive the trees must live to vigorous and venerable old age. A memorial tree of feeble growth and early decrepitude only serves to remind us that it was originally a bad specimen or that it had been badly planted or badly cared for. No excuse can ever be given for planting a tree carelessly or improperly. There may be particular reasons for planting trees closely together, as, for instance, where a rapid upward growth is desired, but for memorial trees ample room is needed. A melancholy example of improper planting in this regard is furnished by the so-called Hamilton trees on Washington Heights, in this city, about which there is so much sentimental discussion in the papers just now. These are thirteen Liquidambar-trees, said to have been planted by Alexander Hamilton to commemorate the original states of the Union. In *Harper's Young People*, last week, there is a good illustration of these trees, and it will be seen that they form a dense clump, standing within an area not more than fifteen feet square, where they could not possibly make a healthy growth. Old as they are, several of these trees are so choked and crowded that their trunks are scarcely eight inches in diameter, although the largest ones are two feet in diameter. None of them, however, has anything like a symmetrical development, and an examination of their tops shows much dead wood in all of them. If Alexander Hamilton or some one else had planted one tree in this spot where thirteen now stand, it would have cast a larger shadow than all of them together now do, and instead of being sickly and moribund it would now be giving promise of another century of vigorous life.

It is outside of our purpose to repeat here the elementary rules for planting trees and for protecting them. What we wish to insist on is that attention to the trees themselves is the matter of paramount importance, while talking and singing of them are of temporary and comparatively trivial moment. Even under the best auspices one day in a year devoted to trees will count for very little. The real advantage from the observance of Arbor Day comes where it is made a pleasing incident in a perennial and ever-growing interest in the study of natural objects. Some of the state horticultural societies have done very wisely in offering to furnish seed and plants under certain restrictions to district schools, in order to encourage the cultivation of flowers and shrubs on school-grounds. Others have offered to school-children prizes for collections of wild flowers and for classified lists of the birds and insects found in their districts. In an Arbor-day circular from Wisconsin we find directions for making and keeping a lawn, which is an admirable idea where the grounds are so large that the whole area is not required for a playground. The essential point is to encourage among school-children a personal interest in trees and shrubs, not simply for their use in making the school-grounds an attractive place, but for the development of habits of observation, which is of itself a liberal education. The habits of investigation which distinguish a man of science from his fellows are the very ones which are natural to young children, and which are too often repressed

in schools, where they should be encouraged. Just now, when all nature is quickened with new life and when the beauty and melody and fragrance of spring are appealing to our awakened senses, every child is eager to respond to the invitation from the woods and fields. The most fascinating objects for study abound by every wayside and in every thicket, and all the alert young faculties need is proper direction and encouragement.

A Japanese Garden.

THERE have been many allusions in recent comments on Japan to the picturesque gardens for which it is distinguished, but, however clear a description may be, it lacks something in definiteness, so that the illustration on page 175 will be of use in helping our readers to form an idea of one of the graceful and harmonious scenes that the Japanese delight in contemplating. In summer, when the sliding front of the house is rolled back, the master sits where he can look out upon his little domain, and the very decorations of his apartment are nicely calculated to harmonize with the character of his garden.

The picture gives us the situation of the buildings, and shows the enclosing stone wall, surmounted by a fence of plaster, with a battened coping of polished wood. Sometimes bamboo, interlaced in a pattern, is used for fences with very agreeable effect, and again hedges of Camellias are employed to enclose the grounds.

In the garden represented, the surface is naturally irregular, but the rising ground in the rear is made more effective by artificial mounds, which have been constructed to vary the slope. A miniature lake, encircled by greensward, and overarched by a light bridge of Bamboo-poles, is fed by a cascade from the hill, shaded by Willows. Groups of the red-flowering Azalea grow at its foot, with rushes and aquatic plants. Volcanic rocks with encrusted surfaces are here disposed to give wildness to the scene, and they are also placed elsewhere about the grounds, or on the borders of the sheet of water for ornament. Flat slate stones are also scattered about the greensward, to serve for paths, being found throughout Japan of convenient size and shape for stepping-stones, for which they are used everywhere.

Climbing the elevations we came to a thatched pavilion, from which there is an outlook upon the garden and upon the distant prospect. Near this, on the right, is a group of evergreens, and on the left we catch a glimpse of a little thicket of Bamboo, and the broad leaves of a Magnolia, the grassy slopes of the elevations being relieved by the smaller mounds, which lead like foot-hills to the turfed level below.

Here are groups of deciduous trees, and mingled clumps of Cypress and Cherry-trees in blossom, the white flowers showing in masses against the dark evergreens. Near the wall, in the foreground on the left, half-buried in bushes, is a windowed summer-house, with a high fence to insure privacy. This is hidden by an angle of the wall from an arbor with an arched entrance, near which stands one of the ornamental stone lamps with which the Japanese are fond of adorning their pleasure-grounds. A shrub in flower, probably the Hawthorn, grows beside the lamp, and also a few dwarf Cypresses. The tall evergreens upon the hill, and also those planted near the buildings as a shelter and screen, are Cryptomerias, the largest and most valuable cone-bearing trees of Japan.

Without the garden is a graveled court, from which a gate and flight of steps lead to the street, and in the corner of this court-yard are a Plum-tree in full bloom, and two Pine-trees, one of which is trained into a conventional form, apparently to overshadow the door in the garden-wall. Here we see the porch where the gate-keeper sits, which affords an entrance to a long low building communicating with the women's quarters, the larger of the two constructions being the dwelling of the master of the house.

There is in this little garden into which the cottages open an effect of harmony and repose. Proportion is well considered, and grace of line prevails, with agreeable masses of foliage where required. Though highly artificial, the tiny pleasure-ground is so simple and quiet, there is such a pleasant breadth about it that we gain an impression of space and dignity and suggestiveness that is often lacking in a far more spacious demesne. It gives a hint for a way of treating a large domain, where the miniature landscape might be reproduced on a more imposing scale with equal effectiveness, or it could be copied with advantage in a suburban villa of limited space, or used to form a surprise in some corner of a large estate.

In the Japanese book from which this illustration is drawn, are many other designs for the treatment of grounds of greater or less extent, which are full of interest, as showing the picturesqueness of the ideas of this artistic people when applied to landscape-gardening. No matter how small his enclosure, the gardener of Japan spares no pains to make his plot of land suggestive as well as beautiful. He will create in the sand of his back-yard a tiny Sierra, or fashion the gravel, by bridges and mounds, and carefully calculated strokings of the surface, into a suggestion of a lake or river. There is apparently no limit to his imagination, and like a child he enjoys his toy and invests it with whatever fancy pleases him. Thus through the mind he gains a larger outlook, and of a trifle makes a semblance of the universe, with that wise and gay philosophy which supplies material lacks by pleasures of the imagination. This cheerful gardener who, with fertile fancy, creates his own paradise, has discovered the secret of content,

And having little, yet hath all.

In the eastern and northern states the danger from fire in woodlands is greater just at this time than at any other period of the year. The snow has melted; high winds have dried the surface of the ground, which is often covered with fallen leaves or with long dry grass and weeds, and the young growth of shrubs and other plants saturated with water has not yet appeared to resist the spread of fire. The conditions, therefore, are favorable for destructive conflagrations. This is the season, too, of rural spring cleaning; on every farm, on every country estate and villa lot, fires are kindled now to destroy leaves and brush, dead wood, and all the other refuse material that has accumulated during the year. It is usually a season of great atmospheric dryness and of high winds; bonfires carelessly lighted or carelessly tended escape control, reach meadows covered with dry grasses or woods strewn with dried leaves, and, soon getting beyond all control, spread to the forest and sweep on until their progress is stopped by a stream too broad to leap or until they are quenched by a rain-storm. Tens of thousands of acres of forest-land are burnt over every spring in the United States by fires started on farms; millions of dollars' worth of property is consumed, and many families are rendered homeless. During the month of April it is not an uncommon thing in some parts of the country to see the sun obscured for days together by the smoke of these fires, and every year at this time the columns of the daily journals are filled with accounts of the suffering and the losses caused by them.

It is necessary to build bonfires, although there are too many of them, and a great deal of good plant-food goes up in smoke in this country instead of being returned to the soil, but the management of such fires should be given to careful and responsible men; they should not be built when the wind is high or very near woods, or in long dry grass. The centre of a plowed field is the best place for a bonfire; it should never under any circumstances be left smoldering at night. This is a lesson we might have learned from the Indians, for an Indian never left a fire burning when he left his camp. The forest and the prairie meant too much to him, and he took no risks which might lead to their injury. His white successors are more indif-

ferent and more careless of personal safety and public prosperity. We have long held the view that there can be no protection for woodlands in thickly settled parts of the country until the community is sufficiently educated about the value of the forest to make possible the enforcement of a law under which town officials chosen for the purpose can have supervision and control over the manner and time of setting brush fires, and which should make it unlawful for any man to build a fire in the open air until he had obtained permission to do so.

It is evident that the value of the forest is better understood and more fully appreciated now than it was a few years ago, although perhaps this hardly appears yet in any perceptible diminution in the number of forest-fires. As a people, however, we are very far from that degree of intelligence and civilization which will permit interference with our action on our own land, and until that time comes the rural press cannot do the country better service than by preaching caution in the building and care of fires in the neighborhood of woodlands.

Notes of a Summer Journey in Europe.—XI.

FROM Copenhagen I went to Cassel by way of Hamburg, and short stops were made at both places.

In most of the German cities visited I was surprised to find the Elm so little used as a shade-tree, but in Hamburg the English Elm (*Ulmus campestris*) is quite commonly planted, and there are some fine avenues of it, forming beautiful gothic arches over a number of streets. Very uniform rows of the Linden (*Tilia vulgaris*) are also to be seen, all the trees being of about the same size, at equal distances apart, and in fine condition. The advantage of planting only one kind of tree in a single line is well shown here, and, altogether, the streets of this city are much better than the average in the matter of shade. Sometimes the foliage of the Lindens, Maples and Elms had a gray appearance, owing to attacks by little red mites, and in a few cases the Lindens had lost many leaves from this cause.

The site of the old fortifications, extending in a semicircle within a part of the city, forms a pleasant, though narrow, park-like promenade and recreation-ground. Our common Locust has been much planted here, and as it is free from the attacks of the borers which specially trouble it in its native land, it attains to fine proportions, some of the trees being three feet in diameter. The White or Silver, the Ash-leaved and the European Field Maples (*Acer campestre*) have all attained fine size. A specimen of the Striped Maple (*A. pennsylvanicum*) was noticed, which is grafted on the Sycamore Maple (*A. pseudoplatanus*) at five or six feet from the ground. Both stock and cion have grown at about the same rate and are now a foot in diameter; but the difference in bark makes the point of juncture very noticeable and forms an unpleasing contrast. The borders of ponds and banks of the streams are often made pretty and natural by grasses, reeds, shrubs and overhanging trees.

The Botanic Garden at Hamburg is arranged according to Endlicher's system of classification. In some respects the collections are not so interesting as those at Copenhagen, and at the time of my visit (August 15th) the garden had a somewhat weedy and neglected appearance. It seemed odd to find the Norway Spruce still labeled "*Pinus Abies*," and the European Larch as "*Pinus Larix*." There are a number of good examples of American trees here, among them *Taxodiums*, Black Oaks, *Gymnocladus*, *Liriodendron* and *Magnolia acuminata*.

Perhaps the most interesting tree in the garden is a specimen of the so-called Byzantine Hazel (*Corylus Colurna*). Our American Hazels are all mere shrubs, and we are apt to think of all Hazels as little more than bushes. *C. Colurna*, however, becomes a tree, and the specimen in the Hamburg garden is perhaps a fair example of what it may be at maturity. This is a tree about sixty feet high, and with branches shading a piece of ground forty-five or fifty feet across. The trunk is two and a half feet in diameter at three feet from the ground, and it divides into three main limbs at five or six feet. The branches diverge at a somewhat sharp angle, and the bark of the trunk is gray and rough. It is a finely shaped tree with rounded top, and at a little distance it has something of the outline and aspect of a small-leaved Linden. Not much space is given to greenhouses, and a *Victoria regia* house is considered the chief attraction.

South of Hamburg the railroad to Cassel passes through the great Lüneburg Heath, a series of sands and bogs densely covered with a thick close growth of Heather (*Calluna*), which had just come into good bloom at the time I passed through, so that the wastes were assuming a purple color. Enormous quantities of Scotch Pine, some White Birch and Alder, and also Norway Spruce, have been planted in various places, so that the country wears less of a barren look than it once did.

Probably no part of Germany possesses and shows such favorable conditions for the growth of trees as Cassel and its vicinity. The park known as the "Auegarten," said to have been designed by Le Nôtre, the illustrious French landscape-gardener, is regarded with feelings of pride by the present generation of the citizens of Cassel. The trees have attained splendid proportions, are in excellent health and vigor, and are generally so planted and grouped as to give plenty of chance for development, and at the same time leave openings which afford many pretty and varying vistas. A better and much more beautiful and picturesque treatment of the water might easily be made, for the banks of the ponds are generally rather bare and uninteresting.

This little park is less known than it deserves to be, and perhaps this is in part due to the fact that the park, water-falls and gardens of Wilhelmshöhe are so near and are so much more attractive to the popular mind. Wilhelmshöhe, with its Hercules, its artificial water-falls, grottoes and fountains, presents a striking contrast to the simplicity of the Muskau Park, which has been already noticed; and when the magnificent situation of Wilhelmshöhe is considered, it is easy to imagine how much more might have been made of it in different hands and with different ideas of landscape-design. The great cascade, nearly a thousand feet in height, or rather in length, at a little distance, looks more than anything else like a gigantic stairway built for the descent of Hercules, though it remains a mystery how Hercules is to get down from his pedestal on the top of the mountain. Leaving out these attractions, however, there are many beautiful and picturesque stretches and vistas in the park, where no offensive artificiality is apparent. There is much quiet natural beauty in the woods of Wilhelmshöhe, and its handsome healthy trees have an attraction for every one interested in dendrology. Before fairly entering the park, on the way from Cassel, one is struck by the fine proportions and vigor of the groups and specimens of Lindens, and for a study of these trees there can be few better places. *Tilia parvifolia* and *T. platyphyllos* are the most abundant and furnish the finest examples, but *T. vulgaris* and *T. argentea* are also growing with them. The last was in full bloom (August 17th) and very fragrant, while the fruit of *T. platyphyllos* was conspicuous by its large, full size.

Within the park proper and on the lower part of the mountain, the Silver Firs (*Abies pectinata*) and the Norway Spruces form the finest and noblest examples of tree-growth to be seen in the region. There are many fine groves and groups of these, many individuals with trunks almost four feet in diameter and perhaps a hundred and thirty feet in height. Some very fair specimens of our White Spruce (*Picea alba*) seem like dwarfs beside the magnificent Norway Spruces, but the first have only been planted about sixty years, whereas the others have perhaps been growing for two or three hundred years. The Norway Spruces here do not give the impression of a straggling or ugly habit, so much complained of in America when the trees become old. Good specimens of the Red Cedar (*Juniperus Virginiana*) have much of the aspect and are about of the average size of those usually seen in New England. Here we find large old specimens of the European White Birch (*Betula alba*), with slender, string-like branchlets eight or ten feet long depending perpendicularly from the branches. These slender, drooping branchlets are a striking peculiarity of old specimens of the Norway Spruce and of this Birch, a characteristic rarely seen in our allied north-eastern American trees. Many of our native trees and shrubs are to be found here, and apparently nearly all such as are hardy grow with the same luxuriance as the indigenous arborescent vegetation. The coldest temperature here rarely, or almost never, touches zero of Fahrenheit, and although Wilhelmshöhe is situated at a higher elevation than the city of Cassel, it is said to be liable to less severe cold in winter. This is accounted for by the presence of the surrounding woods and the open running waters. A little tree rarely seen in cultivation, though early introduced, is our Dwarf Chestnut, or Chinquapin (*Castanea pumila*), which I found here twelve feet high and fruiting freely. Such of our deciduous trees as the Striped Maple, Common Catalpa, Willow Oak (*Quercus Phellos*), etc., are represented by very good mature specimens; while *Pinus ponderosa* and other American conifers are large enough to bear

plenty of fruit. The purple-leaved Myrobalan Plum, commonly known in nurseries as *Prunus Pissardi*, is here a tree eighteen or twenty feet high, and is probably one of the largest in Europe.

Through the kindness of the courteous Hofgärtner, G. Fintelmann, I was shown the collections within some private enclosures, where many of the rarer and choicer plants are kept. A part of these enclosures is devoted to glass houses and frames containing plants with which I am not familiar. Among these may be mentioned very fine hybrids of *Streptocarpus Rexii* and other species, and a magnificent collection of *Begonias* well worth going a long way to see. These *Begonias* are a specialty at Wilhelmshöhe, and some of the single and double yellow flowers are particularly fine. In the collection are some fine forms of the Peruvian *Begonia Davisii* and *B. polypetala*. Much care is taken in propagating and selecting these plants, and they are not distributed, but strictly kept for home use.

Of all the plants in the open air within the enclosures, perhaps the best and most interesting specimens are two examples of the Japanese Umbrella Pine (*Sciadopitys verticillata*), both of the same age and from the same lot of seed. One is fifteen feet high and of erect open habit, while the other is only about seven feet in height, is much more compact and has a broader spread of branches, so that it seems as though an equal amount of growth and development had been expended in this direction as in attaining a height of fifteen feet. When I saw it the taller plant was bearing fruit and good seed. The first cones and seeds were produced five years ago, and the seedlings raised from these show the same tendency to vary and separate into the two forms—one with an erect slender growth, the other with a dwarfier, more compact habit. The cones of the Umbrella Pine are pendulous, and are produced on the upper branches above the male flowers; and, unlike those of the true Pines and some other conifers, they mature in one season. The Wilhelmshöhe plants are not so tall or large as some to be found in other places on the Continent and in England. Though not remarkable as a specimen, another fruiting conifer was *Torreya nucifera*, of Japan, whose egg-shaped fruit somewhat resembles enormous berries of the Yew. The *Torreyas* are rather rare in cultivation, and they are hardly capable of well withstanding climates much colder than that at Wilhelmshöhe.

It was pleasant to see the *Rhodora* thriving here in fine clumps; and a charming little rockery contained, among other interesting things, a quantity of the little Dwarf Cornel, or Bunch Berry (*Cornus Canadensis*), which was still producing a few stray flowers. *Fatsia horrida* has generally been regarded as a rather difficult plant to cultivate, so that it is perhaps one of the rarest and most unusual shrubs in collections. A specimen here was bearing bright scarlet fruit, but the flowers are said to be liable to some injury by late spring frosts. It may be that, besides the cultural attention it gets here, this *Aralia* also finds something in the half-mountainous, temperate and moist situation and climate which distantly corresponds to its native home in north-western America.

J. G. Jack.

Primitive Vegetables of Texas.

IN the spring of the year 1855 a body of French colonists, fresh from the old country, established themselves in Dallas County, Texas, which was at that time very thinly settled. Game was plentiful, fish not scarce, and beef very cheap, but beyond Indian Corn and Wheat no vegetable food could be obtained. As a rule, the French are not a carnivorous people, and therefore the lack of vegetables in variety was keenly felt. True, the colonists had brought along with them vegetable-seeds of many kinds, but when they arrived the season was already too far advanced to permit a proper preparation of the ground, and the weather that year was so dry that hardly anything would grow. The crop therefore was a flat failure, and the suffering colonists were forced to search among the wild plants for some substitute for the vegetables they so highly prized.

The earliest plants to attract their attention in the spring were two species of *Astragalus*, one of them *A. Plattensis*, growing in sandy soil, and the other *A. caryocarpus*, growing in black prairie-land, and bearing early flowers not devoid of beauty, which are succeeded by round, fleshy, sweet pods of the size of a large gooseberry, to which they have some resemblance. These were called buffalo peas, or prairie apples, and they were used as substitutes for garden peas, and rather unsatisfactory substitutes they were. Children, and oc-

asionally grown persons, ate them raw, and in that way they were really more acceptable.

In the way of salads the country was more generous. A true Lettuce was found (*Lactuca scariola*), a perennial, and quite an early plant, which was succeeded by a kind of Dandelion (*Pyrhopappus multicaulis*) and a Primrose (*Oenothera trilobata*). This last is worth more than a passing mention. It is an annual plant which grows in winter and early in the spring, and which produces in long succession large bright yellow flowers, each one of which lasts for a day only. They spring from the ground, having no peduncles, and the plant, which is quite ornamental, has no stems. The large square capsules or seed-vessels are borne in large conical bunches, which are not unlike the pineapple in appearance, and are very striking after the leaves have disappeared. The plant is used as a salad just as the Dandelion is. The Lamb Lettuce was represented by the *Valerianella amarella*, and for Celery an early stemless plant belonging to the Umbelliferae was used (*Peucedanum foeniculaceum*), whose blossoms and leaves much resemble those of the Sweet Fennel, although it tastes like Celery. Two species of wild Onions were also used; these were *Allium Canadense* and *A. Nuttallii*.

Another plant which deserves mention is a bulbous one belonging to the Iris family, and closely related to the *Tigridia*. It is *Nemastylis geminiflora*, and it was found growing abundantly in the black prairies. It produces a small brown bulb that is farinaceous, sweet and palatable, and the hogs were so fond of them that when free they nearly exterminated the species. It is not improbable that with care and cultivation this would prove of some real value as a garden-vegetable, and, as it is, it well deserves a place in the flower-garden. It bears a dozen or more flowers on each stem of a beautiful blue, or sometimes white. Most of these vegetables are little used now since better ones have taken their places; but the four salad-plants I have mentioned are still in use not only by the French, but by the American settlers, who have learned to appreciate their value.

New or Little-known Plants.

New Orchids.

CYPRIPEDIUM × *BACONIS*, Kränzlin, is a secondary hybrid raised in the establishment of Messrs. F. Sander & Co., of St. Albans, from *C. chlorops*, Rchb. f., crossed with the pollen of *C. Schlimii*. It is said to have flowers much resembling the mother plant, and to be of easy and luxuriant growth. The seed was sown in November, 1888, and the seedlings flowered in January last.—*Gardeners' Chronicle*, February 6th, p. 171.

CATASETUM LIECHTENSTEINII, Kränzlin.—A species very closely allied to *C. Trulla*, Lindl., which appeared in the collection of the Fürst Liechtenstein. The pendulous raceme is said to bear about twenty flowers, with grassy green sepals and petals, and a similar lip, with blackish brown on the edges and lower parts.—*Gardeners' Chronicle*, February 6th, p. 171.

CYPRIPEDIUM × *LEDA*, Hort.—A hybrid raised in the collection of John C. Bowering, Esq., of Forest Farm, Windsor, from *C. Harrisianum*, crossed with the pollen of *C. venustum*. It is said to be fairly intermediate in character, except that the purple stripes on the dorsal sepal of the mother plant are almost obliterated, and the sepals somewhat approaching those of *C. villosum*.—*Gardeners' Chronicle*, February 13th, p. 202.

CYCNOCHES GLANDULIFERUM, Rich. and Gal.—A Mexican species, long very imperfectly known, which has flowered both with Mr. W. Bull, at Chelsea, and Mr. J. Charlesworth, of Heaton, Bradford. The male flowers, which are light green, spotted with brown, with a white lip, are borne in a long pendulous raceme; the females are at present unknown.—*Gardeners' Chronicle*, February 13th, p. 204.

CYPRIPEDIUM CHAMBERLAINIANUM, O'Brien.—A very distinct and beautiful species imported from some part of New Guinea by Messrs. F. Sander & Co., of St. Albans. It belongs to the same group as *C. Rothschildianum* and *C. Stonei*, though it has so few characters in common with them as to have been described as the first of a totally new section of *Cyripedium*. Native specimens have spikes

showing from twelve to as many as twenty flowers, the bracts being much closer together than usual. The flowers are yellowish white with rosy purple markings. The petals are spirally twisted, comparatively short, and nearly horizontal, and the pouch much inflated. It is a great

CYPRIPEDIUM × LUCIE, Hort.—A hybrid raised by Monsieur Moreau, of Paris, by crossing *C. Lawrenceanum* with the pollen of *C. ciliolare*. It bears a strong resemblance to the mother plant, though somewhat modified in the direction of the other parent.—*Orchidophile*, 1892, p. 17, with colored plate.

Kew.

R. A. Rolfe

Fig. 26.—The Pepino, *Solanum muricatum*, in fruit.

acquisition.—*Gardeners' Chronicle*, February 20th, pp. 234, 241, fig. 34.

DENDROBIUM O'BRIENIANUM, Kränzlin.—A Philippine species, introduced by Messrs. F. Sander & Co., of St. Albans. The small flowers are yellowish green, and borne in long drooping racemes. It flowered at St. Albans in the autumn of last year.—*Gardeners' Chronicle*, February 27th, p. 266.

The Pepino.

OUR experience in fruiting the Pepino during the past year differs somewhat from that of Professor Bailey, as detailed in a recent bulletin from the Cornell University Experiment Station.* The experiment at Cornell, an account of which was given in *GARDEN AND FOREST* (vol. v., p. 95), seems to indicate that but one fruit sets in each flower-cluster. Of our plants one bore two fruits in the manner described, while the others, cuttings from the first, were much more prolific, bearing six to eight fruits in each cluster. The accompanying photograph represents one of these plants. The photograph was taken on February 25th, and the plant was about three feet high. It will be observed that the peduncles are not elongated to such an extent as they are when only one fruit develops. I have noticed the same trait in the Egg-plant. That is, when fruit fails to set, the stem and calyx are often elongated abnormally.

In view of the natural habitat of the plant, in the highlands, where the temperature is relatively low, and of the fact that the fruits never set well in Florida except during a cool period, it would seem that we have some hints for treatment under glass. Heretofore I have never succeeded in obtaining any fruit, though the flowers were repeatedly pollinated by artificial means. The plants at this time were grown in a Tomato-house with a night temperature of sixty to sixty-five degrees. During the present season the treatment has been very different. The plants were from cuttings started in May. During the summer they were in four-inch pots plunged out-of-doors. In the fall they were removed to six-inch pots and placed in the house. Since then they have been kept in a cool house—forty-five to fifty degrees—and have received no bottom heat. This treatment has proved much more satisfactory than the other in inducing the fruit to set; but, as before, a large proportion of the blossoms fail to set fruit. The lower

temperature seems also to develop to a higher degree the peculiarly rich flavor of the fruit. Professor Bailey compares the flavor to that of a "juicy, tender, somewhat acid egg-plant." With us the flavor has been decidedly musky; so much so, that when tested recently by several parties

* Bulletin 37, Cornell University Experiment Station.

the universal comment was, "much like a cantaloupe." There is, however, an agreeable acidity which is very distinct.

It seems certain that the Pepino will prove a valuable acquisition if we can determine the proper conditions for fruiting it under glass.

Foreign Correspondence.

London Letter.

RANUNCULUS CORTUSÆFOLIUS.—A flowering specimen of this plant, which was described by Sir W. Hooker forty years ago as "unquestionably the handsomest of all the Buttercups," was a special attraction at the last meeting of the Royal Horticultural Society. It was sent by Lord Hylton, of Merstham House, in Surrey, where I am informed it grows well in the open air with a little protection in winter. It is a rare plant in English gardens, notwithstanding its introduction forty years back and the unquestionable beauty of its flowers. It has a large fleshy, tuberous root-stock, an erect stem as thick as a man's little finger, and sometimes four feet high, freely branched above. The leaves are a foot across, slightly lobed and toothed, hairy, as also are the stems. The flowers, which are in large, broad, crowded corymbs, are erect, two inches or more across, golden yellow, varnished or shimmering, as in all Buttercups, the petals of good substance, the fragrance strong and pleasant. The Rev. E. J. Lowe, writing of this plant in *Hooker's Journal of Botany* (vol. ix., 69), says it is a very striking, large and handsome plant, of almost gigantic size and stature in its genus and of a noble appearance. Its enormous Buttercup-like flowers are conspicuous at considerable distances on the ledges within the clefts of high rocks or cliffs in the ravines in Madeira. It is also found in the Canary Islands. Another name for it is *R. grandifolius*. At Kew the plant is not hardy, but the late Mr. Giles Mundy grew it well in his little garden at Farnham. It is curious, too, that, while Mr. Smith stated in the *Botanical Magazine*, under tab. 4625, that it required the protection of a frame or handlight in winter, Sir W. Hooker says in the same place that "it is quite hardy." In favored localities I know it thrives in England. It is worth growing as a pot-plant for the sake of its handsome fragrant flowers which open in March.

SCHIZOCODON SOLDANELLOIDES.—A living example in flower of this very interesting little Japanese plant has lately been sent to Kew by Captain A. Torrens, who collected it while in Japan, and in whose garden in Kent it has flowered probably for the first time in Europe. Its interest lies in the fact that it is very closely related to *Shortia galacifolia*, which, I believe, has been found wild in Japan as well as in North America, and used to be known as *Schizocodon uniflorus*. There is a close family resemblance between this new-comer and the *Shortia*, but the former has a short decumbent stem, shining green ovate, cordate leaves about an inch long, and a two-flowered scape. The flowers are like those of the *Shortia*, but more cupped, and with linear instead of scale-like staminodes. A figure of the plant has been prepared for publication in the *Botanical Magazine*.

DENDROBIUM PHALÆNOPSIS SCHRÆDERIANUM.—The plants recently introduced by Messrs. F. Sander & Co. are proving exceptionally rich in variety both of color and size of flower. At the last meeting of the Royal Horticultural Society a group of about a dozen plants, all in flower, was shown by an amateur, Mr. E. M. Mundy, and among them was one with almost pure white segments, another with mottled segments, and one with flowers of the deepest colors, and exceptionally large in size, measuring four inches across. These flowers were all produced from newly made growths, a fact which proves that under cultivation this *Dendrobium* will grow well—far better than most of the *Dendrobiums* from the same region. We have

plants of it growing freely in a hot moist house, such as suits *Phalænopsis*, but unshaded.

COCOS WEDDELLIANA.—This is the most popular of all the Palms which are grown here for the decoration of rooms, dinner-tables, etc. It is easily grown, assumes an elegant appearance from the first, and it always sells well. Over one hundred thousand seeds of it were sold by auction in London a few days ago. Although discovered by Dr. Weddell in 1831 it was not introduced into cultivation until about thirty years afterward, when L. Van Houtte, of Ghent, distributed it under its present name. A few years later it again appeared under the name of *Leopoldinia pulchra*, and at a still later date as *Glaziova elegantissima*. There is a figure of it in Wallace's *Palms of Brazil*, where it is called *Leopoldinia pulchra*, and described as an elegant Palm, with a stem eight to twelve feet high and two inches in diameter with leaves seven feet long, which, on certain saints' days, are used for the decoration of altars and similar sacred purposes. It is so abundant in some parts that its stems are commonly used for making fences. The seeds are ovoid and one and a half centimetres in diameter.

C. insignis, otherwise known as *Glaziova insignis*, is almost as elegant a plant, the fronds being a little broader in the pinnæ and the stem perhaps a little thicker, otherwise it is quite as strikingly graceful. It has the merit, too, of being satisfied with the temperature of an ordinary greenhouse. There is a good example of it in the winter garden at Kew, which has borne the minimum temperature of forty to forty-five degrees for the last two winters without suffering in the slightest. It would certainly thrive in the open air in the warmer states; for instance, in south California. It is a native of Brazil.

A BAMBOO GARDEN.—This is the latest addition to the special gardens at Kew. Hitherto the hardy Bamboos have been scattered over the garden or grown in a position ill-adapted for some of the kinds. The new garden is about a quarter of an acre in extent and is oval in form, with sloping banks and a large depressed central area. The garden is surrounded by trees, to which an informal belt of shrubs has been added. Beside Bamboos it is proposed to grow in this place all the large hardy Monocotyledonous plants, such as hardy Palms, Yuccas, *Gyneriums*, *Arundos* and *Eulalias*. The species of Bamboo known to be hardy at Kew are the following: *B. Metake*, *B. Simoni*, *B. viride glaucescens*, *B. Quilloi*, *B. palmata*, *B. tessellata*, *B. Fortunei*, vars., *B. nana* (Hort.), *B. nigra*, *B. mitis*, *B. quadrangularis*, *B. Kumasaca*.

SHRUBS FOR FORCING.—Flowers out of season have an attraction for most people. Plants that may be made to produce their flowers at a time when there is a dearth of bloom are of special value in the garden. To know what plants will force well is to be well equipped for emergencies in flower demand. There are, of course, numerous old stagers, such as the old white *Azalea*, *Camellias*, *Azalea mollis*, *Roses*, grandest and most useful of all, and now not considered out of season at any time of the year. Then we all force *Hyacinths*, *Dicentra*, *Spiræa* (*Astilbe*), *Daffodils*, *Tulips*, etc. There are beside these numerous other plants of special value to force, and some of the best of these are shrubs. We use *Forsythia suspensa*, a beautiful plant when forced; *Prunus Pissardi*, *P. triloba*; *Pyrus malus*, var. *floribunda*, whose beautiful wands of white flowers are rendered more beautiful by the rich crimson color of the unopened buds. *Staphylea Colchica* is now as well known as *Deutzia gracilis*, still one of the best of white-flowered plants for this purpose. Lilac, too, is becoming common, and so is *Daphne Genkwa*, the blue Japanese species. The red-flowering Currants are charming greenhouse-plants when forced so that their branches are wreathed in flowers in February. The large-flowered *Laurestinus*, known as *lucidus*, is beautiful when forced. Nothing could be more beautiful than pot specimens of the double-flowered Peaches when forced into flower by the end of February. Well managed, the branches are laden with large Stock-like blooms, beautiful in the mass, and

valuable for bouquets and such like flower-arrangements. *Spiræa confusa* has crowds of bunches of white Hawthorn-like flowers. Many of the early-flowering shrubby *Spiræas* would force well. Guilder Roses are prettier when properly forced than they are out-of-doors. To force flowers simply to get them out of season is a practice with little to recommend it, but to be able to keep up a supply of flowers all the year round for the conservatory and indoor use by subjecting suitable plants to a higher temperature than they really require is good gardening. The Royal Horticultural Society offered prizes for the best collections of forced shrubs to be exhibited this month, but nothing of special value was shown. There were, however, beautiful pot Roses from the Pauls; *Azalea mollis* and Lilacs, besides lovely basketfuls of flower-branches of double Peach and Forsythia from Messrs. Veitch.

London.

W. Watson.

leaf-areas lose their dark green color, and become light green; these portions soon turn yellowish, and at the same time the leaf begins to curl, the outer edge being generally drawn downward. This causes the leaves to appear considerably smaller, which is quite characteristic of the disease. The discoloration of the leaves progresses slowly, while the portions which were first affected gradually die, giving the leaf a spotted appearance. The spots increase in size and their form becomes very irregular, and in this manner each leaflet succumbs. Upon the fruit the first symptom is a translucent appearance of portions of the outer wall. The centres of these portions turn brown and then black, while the disease spreads more or less rapidly at the outer edges, where a border of the translucent tissue is generally found. The fruit borne by diseased plants also appears to be more irregular than that upon normal plants.

The Tomato-plants are grown in boxes, and the manner in which the disease spreads from one to the other is not known. The plants first affected were situated at one end of

Fig. 27.—A Japanese Garden.—See page 170.

Cultural Department.

A New Disease of the Tomato.

ONE of the greenhouses of the Cornell Experiment Station is devoted to the forcing of Tomatoes, and until the past season the plants have been vigorous and have borne well. But last autumn some of the fruiting plants showed signs of disease; they were weaker, the leaves appeared smaller, and the plants assumed a light green or yellow color. The cause of this change was at first not known, but as the disease progressed it gave evidence of a bacterial nature, and these organisms are now thought to be the cause of the trouble. They are readily found in the tissues of affected plants, and laboratory-cultures develop them in large numbers. We thought that this bacterium might be identical with the one which is sometimes so destructive to Potatoes, for the appearance of the disease in the two plants is similar, but Professor Burril, to whom specimens were referred, has just reported that the two diseases are probably distinct. It is certain that the disease can be communicated to the Potato, for diseased Tomatoes have been grafted upon healthy Potato-plants, and the latter are now plainly affected.

The first indication of the presence of this disease in Tomatoes is shown by the foliage. Small, often vaguely defined

the house, and those nearest to them were the next to show the disease. One plant, standing about fifteen feet from the rest, has remained healthy to the present time. It is quite certain that healthy plants will become diseased if they are set in infested soil, for several have been treated in this manner and all are now affected. One plant had discolored foliage in less than three weeks. Others were set in clean soil and they are healthy, although it is about four weeks since the disease first appeared in the other lot.

The boxes in which the first diseased plants were grown were used again for the next crop, but they were treated in different ways, in order to discover some method of destroying the disease. Some boxes were whitewashed, some were washed with the ammoniacal carbonate of copper, others with lye, and others were set out-of-doors to freeze. All were then placed in the house with clean soil, and young healthy plants were set in them. No beneficial effects of the treatments can be seen, for the plants are all diseased. Spraying with copper compounds has also proved useless. Undoubtedly, all treatment must be preventive and strategic. Care should be exercised in securing clean soil, etc., and the immediate removal of diseased plants may prevent the disease from spreading to any serious extent. Possibly this serious disease is identical with the Southern Blight, recently reported by Dr. Halsted in a bulletin of the Mississippi Experiment Station.

E. G. Lodeman.

Fameuse and other Canadian Apples.

THE article which follows was prepared for GARDEN AND FOREST by the late Dr. T. Sterry Hunt a few days before his death, and it has been sent to us by his friend, Mr. George Iles:

Apples, we learn from antiquarian examination, were used for food by the prehistoric dwellers in the lake habitations of Switzerland. Early records of western civilization give constant testimony of the value attached to that precious fruit. The influence of soil and climate on the quality of the grape has been very thoroughly investigated, and we have every reason to believe that similar conditions are not less important factors in the cultivation of the Apple, although the subject has scarcely received the attention which it merits from pomologists. For illustration of this we might mention an apple in the St. Lawrence valley, known as the Fameuse, which is greatly prized for its texture and flavor, and commands a high price for exportation. It is worthy of notice that this apple attains its perfection only in certain soils which come from the slopes of the small hills in the St. Lawrence valley, Mount Royal, St. Hilaire and Rigaud. It is in well-drained soils derived from the crumbling volcanic rocks that the Fameuse thrives best. Fruit of this same variety grown on the clay soil of the valleys near by is readily distinguished, alike in flavor and color, from that grown on the more favored soils.

Disregard of the needful conditions has led to many disappointments in the planting of orchards in this region. It is worthy of notice that the Fameuse trees are not quite hardy, and a certain portion of them are destroyed by frost before they attain the age of bearing. A seedling of the Fameuse grown in the upper Mississippi valley, where it has been named the Wealthy, resists the extreme cold of that region and of the Ottawa valley, but this hardiness has been attained at the expense of the flavor of the apple, which in the Fameuse is very delicate. It may be well here to mention some varieties of Canadian apples which have not received the attention they merit:

The St. Lawrence is an apple of rare quality and texture, which was a chance seedling in Montreal—the original tree still stands in Montreal, though mutilated, to make room for building purposes. The Russian Alexander, which is much finer in quality than either of the two Canadian varieties of the Alexander, is also becoming somewhat rare. The Golden Russet and Pomme Grise are small, but of unrivaled flavor and careful preservation till the month of June. The Bourassa, a large reddish russet of extreme beauty and rare quality, originated in the vicinity of Montreal, but is, we fear, lost sight of. All these apples are worthy of careful attention by pomologists.

An interesting fact in relation to the Rhode Island Greening is worth noting. This apple, which, in my boyhood, was a great favorite in eastern New England, seems in late years to have fallen into comparative neglect there, and in some districts its cultivation has been abandoned. I was therefore pleased to find it a few years since in the irrigated soils in the vicinity of Salt Lake, Utah, where this fine apple seems to have recovered the flavor and the texture which made it originally such a favorite in the east.

Violets.

FASHION can never interfere with the popularity of the Violet. Since the introduction of the Parma and Marie Louise forms of the Neapolitan, the type is grown much less than it once was. Though, on the whole, inferior, both from a decorative and commercial point of view, to the newer varieties, it nevertheless has a conspicuous and in some ways superior merit. From my acquaintance I should say it was not quite so early as the others, but is more floriferous and is less liable to disease, and in this way makes up for lack of size and color. Some attempt was recently made to introduce the Parma, so extensively grown for the Paris market, as a rival to the Marie Louise, the general favorite of England and America, but so far without success. The French variety bears abundant lavender-blue flowers, without any trace of purple, and has not the white markings at the base of the centre florets, which, it is contended, is against the Marie Louise. The fact that the latter is not a perfectly double flower, but often comes with a flat, malformed centre, is, I think, an objection of greater weight. The Parma has, moreover, proved more susceptible to both the leaf and root disease than any other variety. Lady Campbell, a blue form of the Neapolitan imported last season, promised, judging from half a dozen plants here, to be a decided acquisition. The

flowers are superior in form to any of this section. The petals are long, and the flower is quite double to the centre. It is recommended as being a continuous and heavy bloomer, which seems probable. Comte de Brazza, the white Neapolitan, a handsome double-flowered variety of good constitution, has not won popular favor. It is nevertheless worn by a few ladies, and highly prized by them for evening dress.

After close comparison between the Russian Violets and the typical *V. odorata*, I have failed to find any considerable structural difference. Certainly the Giant Czar, the most distinct form of the Russian class, does not differ more from the type than does the Neapolitan; and some of the smaller Russian, such as London and Rawson's White, have a very close resemblance. The Giant Czar and its deeper-colored forms, Welliana and Lee's Victoria, are the best of all the single varieties. They force remarkably well, and as many as three crops have been taken out of one house during one season. This necessitates a large stock of plants, which, however, is easy in the case of this variety, as it multiplies rapidly. The plan requires a low, well-lighted house, kept at about fifty-five degrees, Fahrenheit, night temperature. A batch can be forced into bloom and cleared out in six weeks, ready for another crop.

There is a variety of *V. odorata* growing wild in the southern states, particularly in Florida, which is said to have been imported from England. It is probably somewhat changed through acclimatization. The southern variety under cultivation here blooms very early, being at its best during the last three months of the year. Mrs. J. L. Gardiner, of Brookline, Massachusetts, found a form of this southern variety near St. Augustine, Florida, which has been called the St. Augustine, and it well deserves a distinctive title. It is evidently very free from fertile flowers, and blooms profusely the whole winter. The flowers are not large, but abundant and very sweet. The Schonbrun is another variety of *V. odorata*, which has been confounded with the southern one. It is quite hardy here, and after the first few bright days in spring is a perfect sheet of bloom.

There is much diversity of opinion as to the best method of outdoor cultivation for violets. To my knowledge, good Violets have been grown between Raspberries, under Pear-trees, in light soil, clayey soil, with and without manure, and in full sun. My experience has shown that they luxuriate in rich soil, plenty of moisture and full exposure. Some growers take their stock plants in winter, try rooting the runners, which is a good plan when there is danger of disease, but generally old plants are divided into two or three crowns. Until last year I had kept all runners clear off during summer, but I found where a few had been left, when transplanted into the flowering-bed, along with the old plant, they bloomed well, and will make very good plants for outdoors this season.

A multitude of remedies has been suggested for the Violet disease, but few have stood the test of time. There is no doubt that copper sulphates will stay the disease, but even if the plants recover it is not probable that they will yield many flowers. My Violets certainly were healthy last autumn and have remained so, and bloomed well all the winter. When fairly established, I dusted them with a mixture of black sulphur and guano, which was watered in. I also have given them two waterings with manure-drainings; whether or not this has acted as a preventive of the disease I cannot say; it certainly has increased the vigor and healthfulness of the plants.

Wellesley, Mass.

T. D. Hatfield.

The Spring Garden.

NOTHING in nature is more impressive than the annual change from winter to spring. This phenomenon, as old as the world, one never ceases to witness with interest, or to wonder that one clear perfect day of winter should insensibly change in a few hours into an equally perfect day of balmy spring. The atmosphere seems no clearer, the sun shines no more brightly, yet some subtle change has come to earth and air which we at once recognize but cannot describe. If one were otherwise insensible to the change, the myriad small denizens of the fields and woods would by their various shrill noises make the fact quickly known. A few hours, also, will show a great awakening of vegetation, and sometimes, as in the present season, the change is almost as sudden as the revolution from rest to flower, which we read of in the Arctic zone. The first of the present month brought the spring change, which passed as rapidly into an unseasonable summer temperature. This is always somewhat unfortunate from a gardener's point of view. The small early flowers suffer from the great heat and rapidly decline, while the Narcissi, which have been quietly making growth, come

rapidly into too premature bloom without waiting for full development of foliage. In only three days *Narcissus Pseudo-Narcissus* and *N. bicolor præcox* led the van of Daffodils, followed rapidly by *Ard Righ*, the *Tenby*, *Countess of Annesley* and *Scoticus*, in this order. One welcomes the *Narcissi* at any time, however, for from the time of their flowering till the last of the *Chrysanthemums* in November there should be no lack of useful flowers in the garden if it contains a good supply of bulbous plants for the early year. Good early-blooming herbageous plants are not so plentiful, and reliable ones are, in fact, rather scarce and difficult to maintain in this latitude with its vicissitude of frosts and thaws. *Rock-cress* is one of the few satisfactory things flowering just now. The first of the hardy *Primulas* are just opening, and, of course, *Bellis perennis* expands with the first warmth. The *Hellebores* also are apt to give some flowers now—my garden not being one of those fortunate ones where the Christmas Roses flower amid ice and snow, as so beautifully figured in the catalogues. Some *Snowdrops* are still in full beauty, making a season of five months of this charming flower.

This is a good time to arrange for a water-garden if not already provided for. No feature of gardening is more satisfactory and enjoyable, and no garden should be without some arrangements for growing water-loving plants. If *Nymphæas* are grown it is necessary to remember that the tank should be an aquarium, so that it be properly stocked with fish as well as plants. My tank contains only 150 cubic feet of water, and is only twenty inches deep, so that when the hardy *Nymphæas* were left in last winter, some with crowns within six inches of the surface, it was with considerable doubt as to their safety. The tank was covered with a layer of boards, and a thin covering of leaves over these. There seemed to have been not over two inches of ice at any time during the winter, and with more leaves there would probably have been none. The *Nymphæas*, *Sagittarias*, *Limnocharis* and *Aponogeton* came through the ordeal safely, and only need a replanting in boxes and a little warmth to start them into full growth. Some of the *Nymphæas* start up very quickly. A large plant of *N. chromatella*, which was wintered in the cellar and was entirely dormant, woke up in three days when placed in a pail of water in the greenhouse at sixty degrees. There seems to be no difficulty in wintering hardy *Nymphæas*, and the tender ones after they have made tubers, but some varieties, like *N. Zanzibarensis*, are very unreliable keepers with most growers, and it is to be hoped that some one will explain how they may be wintered with certainty when they have not formed tubers. In my small experience a check from leaving them out too late, or a low temperature at any time, seem fatalities from which they do not recover.

The Water-garden.

AFTER months of anxious waiting April is a busy time in the water-garden, and this year in particular, when severe January weather followed hard after a few softly beautiful days in March, one cannot help feeling some excitement as the covering is cleared away and the effect of the winter upon some water-plants of suspected hardness is examined. This clearing away of all litter is the first thing to be done in water-gardens north of New York, where the tanks have had a covering, and in many cases where the water is deep, it will be necessary to draw off some of it, so that the plants can be more readily examined. In the neighborhood of New York I have not yet heard of any *Water-lilies* perishing on account of the hard winter. *Marliac's* yellow *Nymphæa* has already made large growth as compared with our native *Pond Lily*, and the *Nelumbiums*—*N. speciosum*, *N. nuciferum* and *N. luteum*—are also showing growth above the soil. Little difference can be seen between these *Nelumbiums* wintered under water and those with the water drawn off and covered with leaves and litter alone. Some persons find difficulty in establishing *N. speciosum*, the *Egyptian Lotus*, and the plant deserves attention at once. If tanks are to be built, the work must be pushed. In tanks already in use, the water should be drained off and a top-dressing of rich compost should be given. If this compost was prepared last season of turfy loam and thoroughly decomposed manure, in equal portions, it will be all the better. The compost to the depth of three inches may be placed directly upon the accumulation of dead leaves, where there is any, and upon it should be spread a dressing of clean sand.

If fresh roots are to be planted and the tanks are not ready or the weather is yet too cold, it will help a great deal if the plants are started in tubs, where they can be sheltered in excessively cold spells, to be planted out when settled warm

weather comes and growth is active. Dormant roots should not be set in deep water, nor should growing plants have their leaves submerged. Roots dormant or just starting should be placed in tanks and covered with about six inches of water, which should be gradually raised as the plants advance. If it is desirable to set them in ponds or lakes, half-established plants may be placed near the edge, where they will be but a few inches deeper in water than where they were grown before. They require but gentle pressing in the mud, but where they show any tendency to rise a few bricks or stones will keep the roots in position until they take hold of the soil. Detective duty against musk-rats should be unceasing, for should these animals once get a taste of the plants they are doomed, and the same is true of *Nymphæas*. I am also of the opinion that turtles eat the buds of *Nymphæas*, and just now I am keeping them under close watch until convinced of their friendliness. Where the hardy *Nymphæas* need to be thinned out this work should be attended to at once and top-dressing should be given them, as has been recommended for the *Lotus*. Where new plants of *Water-lilies* are to be set in a tank they should have at first no more than six inches of water, until a stronger growth makes need for more.

Dongan Hills, N. Y.

Wm. Tricker.

Primula Sieboldi.

THESE Japanese Primroses deserve a wider cultivation than they now enjoy. They are easily grown, soon form large clumps, have handsome foliage, flower freely, and are in full beauty from the middle of April to the middle of May, when there are not many flowers of any kind to be had. Since they flower so early, it is better to plant them in sheltered nooks, where they will be protected from cold winds, or to keep a temporary frame over them from the time they begin to grow till the bloom is over. Give air at all times during the day and mild nights, and take the lights off on calm days. This little extra trouble is well repaid by larger flowers of a brighter color, produced a week or fortnight earlier. A fairly light soil, well enriched with decayed leaf-mold or stable-manure, is well suited for their culture, but is not essential. I have seen these Primroses flourishing in full sun and in partial shade, but they last longer in beauty in the shade. A top-dressing of well-decayed leaf-mold or soil should be given in the fall, as the crowns are often above the soil when the plants have done growing. When hard frost sets in a slight covering can be given of boughs, with some litter thrown on the top (so that the litter does not rest heavily on the soil), or a temporary frame covered with a wooden shutter or boards can be used. Protection from frost is not necessary unless the winters are very severe or on soils where plants are much lifted by frost. The covering should be taken off as soon as frost is out of the soil, and where a frame is used a light can be put on.

The following varieties are distinct: *P. Sieboldi*, the type, has large umbels of bright magenta flowers with light centre; *Intermedia*, improved, has bright reddish crimson flowers in large umbels, freely produced; *Lilacina* has large fringed flowers, lilac, feathered with white, and light centre; *Lilacina marginata* has bold flowers, nearly as large as a dollar, with petals overlapping, the exterior of the flower light slate, the interior white, margined and slightly feathered with lilac; *Magenta Queen* has large dense umbels of clear magenta flowers, slightly fringed, and is one of the first to flower; *Rosea alba* bears abundantly flowers whose exterior is light, interior white; *Rosea striata*, flowers light lilac, shaded and striped; *Violacea*, flowers reddish violet, borne freely in rather loose umbels.

Charles H. Rea.

Correspondence.

Mid-March in Northern California.

To the Editor of GARDEN AND FOREST:

Sir,—After an unusually mild winter there came in late February a series of clear warm days, with pleasant nights and a midday temperature which rose to eighty degrees in the shade. This continued for three weeks, and its effect on an already advanced vegetation may well be imagined. *Narcissi* were in blossom by the middle of February, and are now (April 1st) nearly gone, and so are *Hyacinths*. Early *Tulips* are well along; *Violets*, *Primroses*, *Verbenas*, and the whole line of spring flowers are in the full tide of bloom. *Rose-bushes* are a mass of buds, and in sheltered positions a few are in flower. At San Francisco, *Callas* and *Roses* are in full bloom, *Japan Quinces* have come and gone, *Laurustinus* and *Photinias* in

bloom, and the Persian Lilac nearly so. I saw the beautiful St. Bridget Anemones in full blossom over a month ago. Self-sown plants of Drummond Phlox are now in blossom. A striking feature of the spring blooms in California are some of the Australian Acacia-trees. Common here is *A. molissima*, specimens of which a month ago were great masses of yellow bloom, scenting the air for blocks around.

Wild flowers are over a month ahead of time. In February the Manzanitas were in full flower. These bushes are a feature of our scenery, growing in uplands and mountains in large dense masses, and this year they made an unusual display. *Ceanothus divaricatus*, very common in the chapparal growth, is now white with blossoms, and the Madroña is in bloom at this very early date, although May is nearer its proper season. In the open fields our common Buttercup is flowering in masses, and *Nemophilas* common. *Castilleja parviflora*, a dark red Painted Cup, is plentiful in the woodland. Everywhere the bright yellow flowers of *Calandrinia* can be seen peeping through the grass. Of *Erodiums* two species are very common here, and their pink flowers are everywhere. Within a week I have seen some flowers of our state emblem, the *Eschscholtzia*, or California Poppy. There is a second species of *Ranunculus* now blossoming plentifully in wet lands. In leaf and root it very closely resembles the garden varieties, but the flowers are yellow. *Oenothera ovata*, one of the sessile species, is flowering abundantly. The seed-pods of this species are formed several inches below the ground-level. I have seen several blooming plants of the Scarlet Larkspur, and a large plant of this in a wild bed is one of the prettiest things I have in flower now. In a cool situation and loose rich soil, few plants will give better satisfaction. In rock-work it is perfectly at home, and cliffs all aglow with its flowers are among the brightest Californian scenes.

One of the prettiest early flowers is *Mimulus Douglasii*, a tiny annual with a flower nearly two inches long. In my garden the native bulbs are unusually precocious. The first to bloom was *Scoliopus Bigelowii*, which was full of bloom at Christmas, and in a spot where it scarcely received the sun at all. The numerous flowers are produced on slender scapes, and are lined with brown and purple—more odd than pretty. The leaves, which at blooming are quite small, develop later till they are five or six inches long by two to three broad. The *Trilliums*—*T. sessile*, var. *Californicum*, and *T. ovatum*—were in blossom very early. The first is truly a beautiful plant. A specimen at hand shows petals three inches long, with the leaf five inches across. With us the petals are white, with more or less purple in the throat. Near San Francisco all range from rose-color to purple. I have never seen one here of a rose or purple color until this season. A plant which last year was pure white, but which stands where it did, under the shade of a Cypress-hedge, and is never reached by the sun, is now rose-purple. It is common for this species to throw up several stalks from one root, making a fine clump. *T. ovatum* is pure white, and very near to the eastern *T. grandiflorum*.

I bloomed three *Erythroniums* this season. *E. grandiflorum* (*E. giganteum*, according to Mr. Watson's revision of the genus published last spring) is a very free bloomer and easily grown. I find shade necessary to secure the finest flowers. This season I had a bed of *E. Hartwegii*, a rather rare species. The flowers are much the same as those of *E. giganteum*, but instead of being in a raceme each is borne on a slender scape, giving a very pretty effect. Smith's variety of *E. grandiflorum* is always beautiful in flower, but one could wish its blooms were borne more abundantly. As far as I have seen, it is a strictly one-flowered species. It is at first pure white, becoming rose-colored. A soil composed of equal parts of chip, or leaf-mold, and sand suits these *Erythroniums* perfectly; and if planted in a sunny position, the shade of a lath-frame or cloth sash will bring out the flowers in fine shape.

The *Fritillarias* have all done well in a loose soil of sand and mold. I blossomed a rather striking variety of *F. lanceolata* this season called *Gracilis*. The blossoms are more open than in the type, and the segments acuminate. It is very dark, many of the blossoms being nearly black. Held to the light it shows wonderfully rich colorings in dark red and purple. *F. biflora* is a species which takes especially well to cultivation, thriving in any loose rich soil and blossoming freely. The blossom, unlike those of most *Fritillarias*, is not mottled, but the coloring is in fine lines. But of the Californian *Fritillarias* none approach *F. recurva*, some specimens of which have borne thirty-five of its scarlet blossoms to the stalk, and are worthy to be compared with the Lilies for beauty.

But one *Brodiaea* is in blossom so far, the violet-headed one. Nearly all are budded at this very early date. Last year I gave the readers of GARDEN AND FOREST my methods of growing

Calochortus. We learn by experiment, and last year taught me one valuable lesson. I had been giving *C. venustus* ocular rather good loose soil, but one lot was planted in a poor yellow clay loam, a soil that baked like a brick. That lot excelled all others, giving fine stalks, large flowers and perfecting large bulbs. This season all my plants of that variety are in a clay loam, sifted, and I have never seen a finer growth. The same treatment should apply to all the varieties of *C. venustus* and to *C. luteus* and *C. splendens*. In richer soil I find the bulbs do not ripen in a healthy way.

Carl Purdy.

Notes on Grafting.—III.

To the Editor of GARDEN AND FOREST :

Sir,—It has been shown that for successful grafting a sufficient number of cions should be set to sustain a free circulation of sap and to keep all sides of the stump alive. The grafts, cut in February or March, and kept in moist earth in a cellar, should not be set until growth begins in spring and buds are bursting. The waxing of all cut surfaces, clefts and abrasions must be complete, and for this purpose liquid wax is preferable. To make this, take, say, one pound of rosin, one-fourth pound beeswax, one gill linseed-oil. Melt these together and mix. The wax should be of such temper that when cold it will be hard, yet tough—that is, not liable to fracture, as will pure rosin. It may be tested for use by dropping some of the melted wax on a chip and letting it cool. If it then prove too soft, add a little more rosin; if too hard, a very little more oil. The wax may be kept in a small iron kettle.

After setting, say, fifty grafts, warm the wax until liquid, but not scalding hot, and apply with a small paddle or a cheap paint-brush. Cover all wounds and the upper ends of the cions. It is a simple thing to shave a graft's lower end like a wedge and stick this into the cleft in the stock so that the inner barks of graft and stock may meet. If carefully waxed it will almost surely grow. I have set a thousand grafts a day, not using any especial care, except in the waxing, and had every graft grow. In my Pear-orchard are grafts which I set by simply driving a quarter-inch chisel slanting downward into the side of a limb and driving a wedge-shaped cion into the opening made by the chisel as one would drive in a peg, and then waxing. After a year's growth of the graft the limb can be sawed off above it in May or June, sloping downward behind the graft. The cut surface, if waxed or painted, will soon heal over. I have grafted Grape-vines successfully by boring a hole downward in the stock with a bit slightly smaller than the cion; then driving this into the hole as a peg, far enough for bark of graft and stock to join. Cover with moist earth, or, if high on the stock, with wax. After the graft has started saw off the vine.

Thousands of Apple and Pear-trees have been planted which have been grown from grafts set in root-cuttings, or from grafts or buds set upon the sprouts which spring up from the lateral roots of orchard trees where these roots have been torn by deep cultivation. Around a tree disposed to send up these sprouts from its lateral roots may be found several hundred of such growths springing up over a circle, say, twenty feet in diameter.

When there was large demand for nursery stock, and it was useful to have grafted trees as soon as possible, on account of the money they would bring, I have seen nurserymen's agents grafting or budding these root-sprouts by wholesale. Next year they were dug, separated, planted into nursery-rows and soon marketed as "grafted stocks."

Trees thus grown from the lateral roots of the parent tree are apt to be only superficially rooted; they will never have tap-roots penetrating deeply into the subsoil, but will stand flat-footed on top of the ground. They are apt to be injured by winds and droughts and cannot be durable, because they lack a good foundation. These defective trees may be known in the orchard by their tendency to throw up sprouts from their roots.

Sometimes trees in the orchard are damaged by sunscald on the southerly exposure of their trunks. Many of my grafted Apple, Pear and Cherry-trees have succumbed to this injury. On uprooting them I have found them all flat-footed, having no tap-roots. This observation led me to examine the roots of those trees that had escaped this damage, standing in the same orchard and subject to the same conditions. These trees all had tap-roots reaching deeply into moist soil, and thus sustaining vitality during intense surface-droughts.

The teaching of this is to plant only trees grafted on seedling stocks. The seedling naturally develops a tap-root and tends to renew it when it is cut off. A tap-root will never

start from a cutting, a layer or a cutting of a lateral root. This is exemplified in the root-system of Grape-vines which are grown from cuttings. These have their one or two tiers of lateral roots, starting from the buried nodes of the cutting. Thousands of vines have been extirpated in vineyards in south Jersey, and no one ever saw a vine with roots much deeper than the foot of the cutting. On the other hand, I have Grape-vines, grown from seed, with roots penetrating straight downward six or eight feet.

The occasional failure of grafted trees may be explained by this fundamental defect in their root-system. The grafts have been worked upon root-cuttings or root-sprouts. There is no reason why a graft properly founded upon a seedling stock should not be as vital and durable as if the entire tree had grown from the seed.

To have a naturally durable orchard, plant the seed where the tree is to stand and graft it there.

Vineland, N. J.

A. W. Pearson.

Impressions of Leaves.

To the Editor of GARDEN AND FOREST :

Sir,—Many years ago, after seeing some rather indifferent impressions of leaves, taken by means of a pad saturated with coloring matter, it occurred to me to try what could be done in the same line with common printers' ink. The result proved to be much better than was expected. Where the leaf was not too rigid, and had a tolerably flat surface, the impression was not only distinct in outline and venation, but showed the peculiarities of the surfaces of the different Oak-leaves, for example, so clearly that it was quite as easy to distinguish the species from the prints as from the leaves themselves.

Not only could ordinary leaves, like those of the Oaks and Maples, be printed in this way, but many very delicate Ferns, with a little care, were beautifully delineated, as will be seen by the samples I send you. The Oak-leaves were printed some thirty years ago, and the Ferns about twelve years later.

The process was very simple, and I will give it, as it may be both interesting and useful to some of the younger readers of GARDEN AND FOREST, should they be inclined to try it. They will have an enduring reproduction from actual life, which is always ready to be used for study or comparison.

With a small round dabber, like an old-fashioned pincushion, made by stuffing cotton in the hand part of an old glove, the ink is tapped on the side of the leaf to be printed. To apply it evenly the ink should be rubbed with the dabber smoothly over the surface of a plate or flat piece of glass. When every part of the leaf has been inked it is laid on the paper and the two pressed together by placing them in a magazine or letter-book, and using an ordinary copying-press or any other means of applying a strong even pressure.

Where the leaf is firm, as in the Oaks and Maples, the same leaf may be used several times in succession, and often with the result of obtaining a better impression, and if desired several leaves may be printed on the same sheet at one time.

Santa Barbara, Cal.

Hugh D. Vail.

[The impressions which accompanied this letter are beautifully distinct and uniform. They were taken on heavy smooth-surfaced writing paper.—ED.]

Recent Publications.

The Rescue of an Old Place. By Mary Caroline Robbins. Houghton, Mifflin & Company, Boston and New York. 1892.

To most readers of GARDEN AND FOREST this book will need neither introduction nor recommendation, for it is practically a reprint of the series of articles which, under the title "How We Renewed an Old Place," appeared in these columns during the past year and achieved a conspicuous success.

We are tempted, however, to speak somewhat at length of the volume for the benefit of new subscribers and to refresh the memory of older ones, for even those who are familiar with its contents should be reminded that a good piece of work appears to better advantage in book-form than when scattered through the columns of a periodical. Moreover, Mrs. Robbins' chapters have a practical as well as a literary value, and they will be more easily referred to when collected into this pretty little book.

A very pretty little book it is, with a simple but artistic cover of gray muslin printed in silver, and with good paper, attractive type and generous margins, which give room for a useful running index of the contents. Mrs. Robbins has now prefaced each chapter with selections from poets, old and new, and they are chosen with so much taste and feeling that, as

we pass from chapter to chapter, they put us in just the right mood for the pages which are next to come. One of these quotations, by the way, we cannot refrain from reproducing, for it gives an interesting proof of the analogy in mood and even in expression which may exist between poets very widely separated in time and nationality. This stanza runs :

All the fields which thou dost see,
All the plants belong to thee ;
All that summer hours produce,
Fertile made with early juice,
Man for thee doth sow and plow,
Farmer he, and landlord thou !

Does it not sound like a veritable bit of Emerson ? But it was written by one Anacreon, whom we are apt to think of as a very different sort of person. There is only one feature in the make-up of the volume which might be criticised. In a journal like this, specially devoted to plants and their uses, or in a scientific work of which they are the subject, it is fitting that even their common names should be printed with capital letters. But it is open to question whether this somewhat technical precedent should have been followed when the essays, with their distinctive literary as well as technical value, are cast into book-form for general readers.

We shall not dwell upon the practical value of Mrs. Robbins' record of her successes and failures as a designer and gardener, since this will be quickly discovered by all who feel the need of help or sympathy in similar labors. It is even pleasanter to speak of the literary charm of the book, which seems to us not only high in character, but individual in kind.

Our readers have often been told that delightful writing about nature seems the birthright of New Englanders, and have often had their attention called to one book or another which treats of wild nature in some peculiarly attractive way. On the other hand, we are familiar also with books entitled to rank as literature which recite in a gently humorous manner the trials and triumphs of the amateur gardener—books, among which Mr. Warner's *My Summer in a Garden* holds a leading place. But in Mrs. Robbins' book we find an intermingling of many different moods, a constant change from one point of view to another, a condensation of all the varied experiences and emotions that long, busy, and yet contemplative summers and winters in the country can bring, which, we think, gives it a distinct and most attractive individuality. Her observations are not confined to the acres of the old place there. They extend over the beautiful landscapes which lie around them, and include the whole realm of nature, as it has come before her eyes and impressed itself upon her memory. Man's aims and their results are her nominal theme ; but the works of God as a whole, and their influence upon the human soul, is the subject which really occupies her. And it is as surprising as it is delightful to see how she weaves the personal and the general, the practical, the æsthetic and the poetic into the woof of her chapters, so that a discordant note is never felt, and the picture left upon our minds of that corner of the world which she inhabits is as broad in general effect as it is distinct in detail, while the central figures, herself and the companion whose presence we always feel, soon become well-known and pleasant friends. Of course, mere literary skill would not accomplish so much as this. Behind the graceful mastery of word and phrase there lies a sensitive eye, a keen and cultivated mind, a spirit that responds to every poetic suggestion in books or nature, and a sense of humor much more quick and hearty than is often combined with these other qualities. The greatest charm of the book, we have said, is its variety, woven into a harmonious whole. And this variety exhibits itself not only in the themes touched upon, but in the moods through which they are viewed. One never knows in turning a page whether the next sentence will be prettily poetic or instinct with a true sentiment that never degenerates into sentimentality, or whether it will make us laugh instead of smile. The contrast between such a chapter as the one in which are chronicled the web-worm and his devastations and the one entitled "Suggestions of the Waning Year" is very great, and yet it is contrast merely, not discord ; and this is due to the fact that the author seems less to change from one mood to another than to dwell in many almost simultaneously, as finely susceptible minds are able to do. Her most humorous passages are restrained by an underlying seriousness of feeling, and her most reflective ones are enlivened by flashes of humor.

Of course, writing of this sort cannot be described in writing of another sort, and even lavish quotations would not do it justice. We can only say, therefore, that while the *Rescue of an Old Place* will be found useful reading by many persons, it will be found very delightful reading by all who, whether they have acres of their own or not, can sympathize with the expe-

riences of an intelligent and susceptible mind in the presence of nature, or can enjoy really good and graceful writing upon any subject. And the true lover of nature and books will be glad to put this new-comer upon his favorite shelf, whether its row of big volumes and small begins with Evelyn or only with Thoreau.

Notes.

The Spice-bush is already brightening the brook-sides near this city with its abundant yellow flowers.

The best varieties of Sweet Corn are comparatively late. It is well, however, to plant a little of the hardier kinds for extra early use, but we have not yet tried any of these varieties which are satisfactory as to quality.

The Peabody Museum of Archæology announces that the Serpent Mound Park, in Ohio, established to preserve the most interesting of our prehistoric relics from destruction, has been completed, and that the discriminate cutting of timber from parts of the land, together with the sale of the hay-crop, will assist in defraying the expenses of its maintenance.

At the late Philadelphia flower-show some specimens of *Ficus elastica*, which were exhibited by Mr. W. K. Harris, attracted much attention from their bushy habit. Usually, this plant is grown with a single stem, but Mr. Harris' plants branched out at different points along the central stem, so as to present a tree-like appearance. Ordinarily, this branching habit is brought about by cutting off the main stem, but in these plants the branches seem to have been forced out by some cultural device.

The last number of *Meehans' Monthly* has a word of praise for our native Bird's Foot Violet (*Viola pedata*), which is spoken of as one of the handsomest of the family for garden purposes. Not only does it thrive well in borders, but it seems capable of furnishing a great number of beautiful forms, as it grows wild in different colors—white, rose-color and the like. There seems to be no reason why, with some care and selection, it might not furnish as many varieties as the Pansy has. Among some of these Violets, indeed, there are forms now which have a striking resemblance to Pansies with their two upper petals dark crimson and the three lower ones of a violet-blue.

Rev. G. H. Engleheart writes in a recent number of the *Gardeners' Magazine* of *Iris Bakeriana*, that it flowers almost as early as *Crocus Imperati* and about the same time that the most beautiful of the Grape Hyacinths (*Muscari azureum*) appears. It is somewhat expensive, but an excellent example of the paradox that high-priced goods are often the cheapest. Two years ago Mr. Engleheart invested three shillings and sixpence in a not very promising-looking bulb of *Iris Bakeriana* in a tiny thumb-pot. This was turned out into his border, and the next February it gave him one fine flower, which the year after increased to seven, each flower representing a bulb, and now, in its third season, it has formed a fine clump.

Mr. Theodore L. Mead writes to the *Florida Agriculturist* that at his place in Orange County, Florida, *Dendrobium nobile* has proved practically hardy. Some plants on the trunk of a Palmetto have been out three winters and have endured a temperature of twenty-five degrees several times, and once still lower, with very little injury. Sharp frost in January of this year cut off one half-grown shoot, but did not injure another alongside of it, nor did it hurt the old pseudo-bulbs or young flower-buds just opening. This frost cut down large Guava-bushes to the ground, and many of the tenderer *Phoenixes* lost all their leaves. Besides the *Dendrobiums* on the Palmetto, he has others in the woods, both on the ground and on tree-trunks, and these were untouched.

At a meeting of the fruit-growers of Ontario two apples were exhibited which were the result of a careful cross-fertilization by Mr. P. C. Dempsey, between the Golden Russet and the Northern Spy. The first of these, No. 90, was specially commended by the Fruit Committee for appearance, solidity, flavor and keeping quality. It seems an almost perfect apple for export, not too large, of a clear dark-red color, such as the foreign market demands, and its very solid flesh enables it to be packed firmly and carried well. The apple, No. 87, is rather later, and does not reach its best quality till after New Year's. It is larger, and quite as well colored and beautiful. Both of these apples have very small cores. The fact that they are not chance seedlings, but have been produced by careful selection from parents of known qualities, is certainly an encouragement for those who are devoting them-

selves in a studious way to the production of new fruits by careful breeding.

"Experiments by Herr Regel," says a recent article in the *Popular Science Monthly*, "with reference to the influence of external factors on the odors of plants, show that the most important is the indirect influence of light on the formation of etheric oils and their evaporation. Heat and light intensify the fragrance of strongly fragrant flowers, which in darkness is lessened without quite disappearing. When the whole plant was darkened those buds only which before were fairly well developed yielded fragrant flowers; the others were scentless. If, however, only the flowers were darkened, all were fragrant. Other plants open their flowers and are fragrant only by night. When these plants were kept continuously in the dark they lost their scent as they lost their starch. When brought into the light again both starch and fragrance returned. Besides light, respiration has a decided influence on the fragrance. In general, the opening of flowers coincides with their fragrance, but there is no necessary connection between these phenomena."

From some experiments with nitrogenous fertilizers on pasture-fields made at the Storrs School Experiment Station, in Connecticut, it appears that fertilizers containing potash or phosphoric acid alone are less effective for grass than if they have some available nitrogen in addition. The grasses, such as Timothy, Red Top and the like, must be classed as "nitrogen consumers," while Clover and the legumes are now called "nitrogen gatherers," since it seems to be accepted that in some way they gather nitrogen from the air. It would seem desirable, therefore, that fertilizers for pasture, grass-lands and lawns should contain a considerable quantity of nitrogen in a readily available form. Such fertilizers not only increase the total yield of grass, but they also increase the percentage of protein in the crop. Since it is protein which makes blood, bone, muscle and milk, and as this is the most important and costly ingredient in food and apt also to be deficient in feeding-stuffs, the increase of this substance is a matter worthy of consideration and a strong additional argument for the use of nitrogenous fertilizers.

F. R. Pierson writes to the *American Florist* that Bermuda Easter Lilies are often left too long after they are ready to be cut. The proper plan is to cut the flowers as soon as they are sufficiently open to allow the pollen to be removed, to put them in water and set them away in a dark cellar. The flowers will then never become transparent or papery, but have the desirable waxen appearance which gives them their highest value. Of course, this refers principally to the smaller-sized Lilies grown for cutting, on which there are from two to four flowers on a stem. It will be found that when the first Lilies begin to open on the stem, if they are cut and treated in this way, the remaining buds will open even better in the water than they will if they remain in the greenhouse, while the first flowers will keep in better condition than if they had remained in the heat and sunshine until the other flowers had opened. Potted plants should also be placed in a darkened greenhouse, a cool shed or a cellar when their flowers are opening. For transportation the flowers should be packed with a little cotton as tightly as possible, and they should be absolutely dry, because the least moisture will discolor them. Lilies properly cut can be kept for a fortnight without injury if they are in a place where there is no condensation of moisture. When they show any sign of flabbiness they should be removed from the jars and the stems freshly cut, and they will shortly be as good as ever. On arrival at their destination, after a long shipment, they should have their stems cut and be placed in water in a dark cellar for half a day before using, and they will be greatly improved.

Catalogues Received.

The Yellowstone Park.

THE men and women who take an intelligent and active interest in Yellowstone Park are comparatively few, widely scattered throughout the country and not organized for any united aggressive or defensive policy. Here and there a far-sighted man appreciates the immense value which such a reservation will be to the country in the future, and there are a few enthusiastic tourists who have camped in and around it and have acquired a genuine affection for the place, but the great body of our citizens very naturally are absorbed in interests which are nearer home, and they have little time or energy or thought left after their daily labors for anything so remote from their present and personal interests. One would think the Congressmen of the country, whose duty it is to look after the affairs of the nation, would give studious attention to the great reservations of public land which belong to the people which they represent. But they, too, are engrossed with other matters which are of immediate importance to themselves or to their constituents, so that the parks and public forests receive a small fraction of their attention.

There is a small group of men, however, whose interest in the Yellowstone Park never sleeps, for it is an interest born not of public spirit, but of selfishness. This is the partnership whose lobby is working now, as it has done in the last Congress and the one before, to confiscate a portion of the park for private use. It is not a scheme to provide railway facilities for any particular section; it is a scheme to allow no railroad but one through the park, and then to control the franchise. Of course, this project is utterly bad, against public policy generally and against the interests of the park particularly. It has been opposed by every Secretary of the Interior for eight years past, and by every one else who has any genuine interest in the park. The best-informed observers believe that it is primarily a job to get from Congress something which can be sold for cash.

This year, instead of loading the bill to establish the boundaries of the park with a rider, the lobby has introduced a separate bill asking for a right of way through it. A majority of the Committee on Public Lands in the House has been secured, and the bill has been reported favorably. And yet this park belongs to the nation, and not to this set of railroad speculators. Every man in the country is part-owner of it; every man has a right to the protection of his own property, and every man should in some way make a vigorous protest against this condemnation of public property to private use. It is, therefore, the duty of every one who reads this article to write at once to his representative and request him to see that this measure is stopped where it is.

Besides this Montana Mineral Railway job, there has been reported in the Senate a bill which cuts off about one-half of the forest-reservation which adjoins the park on the east, and also cuts off the south-west corner of the reservation on the south. It will be remembered that this reservation was set apart by a proclamation of the President under the power granted to him a year ago, and Congress is now considering a measure to enlarge the park so as to include this reservation. This bill is nominally in the interest of the people of Wyoming, who wish to retain control of this forest, but really the people of Wyoming have greater interest in preserving this forest than any other people of the United States, for it will insure the preservation of a forest which will almost certainly be destroyed if the national protection is removed from it. A most serious mistake is that of cutting off the south-west corner of the forest, which is done, as it appears, in the interest of railway corporations, simply because they think they may some day want to pass that way. No survey has been made, and probably there will never be any occasion for going through this region. If any such railway line were needed it would be much easier and better to pass on the south side of the Tetons than to go around on the north side. Of course, the mining-prospectors and timber-gatherers have an interest in reducing the reservation, but experts declare that there are no mining properties of any serious value in this portion of the reservation which it is desired to hand over to destruction.

It is high time that the whole country should be aroused to face this matter as it stands. Here are two bills favorably reported, both of which are inexcusably bad. No railway franchise should be allowed within the park under any condition, and this particular one is essentially vicious all the way through. The whittling down of the forest-reservation is another serious attack on public rights which should be strenuously opposed. Instead of diminishing this area, other reservations should be established as rapidly as they can be intelligently located and their boundaries judiciously determined. The time will come when a broad and strong current of public opinion will hold Congress to its duties in this direction, but until then it is the duty of every one to appeal to his representative and to any other member of Congress with whom he may have influence to protect from spoliation these few isolated remnants of our great forest-domain which by a fortunate chance have been set apart to be held forever as public property. In this way alone can their permanent safety be assured.

For nearly a month the proposed speedway in Central Park has been a topic for animated discussion in the newspapers of this city, and the writers for the press, called upon to give a reason for the faith that was in them, have found it necessary to pay studious attention to many of the problems in the design, construction, maintenance and management of public parks. We have often called attention to the vague and inconsistent views as to the true functions of city parks which are held even by intelligent persons, and therefore this discussion of first principles has had a genuine educational value in the clearing away of misconceptions. Only a few years ago the President of

the Park Board in this city attempted to justify a project of his to fill up with carpenter-work one of the fairest dells of the park by calling the spot "a piece of unimproved ground," and it seems to be a prevalent opinion that land which cannot be driven over or trampled on or covered with structures of some kind can serve no useful purpose.

Of course, this argument was used by the advocates of the new road, who stated that it would be laid out in an "unused" portion of the park. One of the Park Commissioners happily exposed this fallacy in a letter addressed to the Legislature to urge the repeal of the act authorizing the speedway. He stated that there can be no "unused" portion of the park; that its green fields are fulfilling their highest use when no foot treads upon them; that the park really exists for its landscapes, and that its elements have their highest value as they combine to give it the charm of a rural scene. It is a place to look at primarily, and its untrodden greens and unentered groves are the very foundations of its beauty. This is a lesson which cannot be too often or too strongly insisted upon. All classes and every interest which have ever clamored to get possession of some portion of the park have urged in favor of their encroachment that "the park was made to use, and not to look at," when the fact is that its primary use is to be looked at; that it is beauty which gives it value, and a value which is not sentimental, but real, fundamental and practical.

Notes of a Summer Journey in Europe.—XII.

SELDOM have I spent time so pleasantly and profitably as I did two or three days at the Botanic Garden, or little arboretum, of the Government Forest Academy at Münden. Both the pleasure and profit which I derived were largely due to the fact that I was under the guidance of Dr. H. Zabel, whose modesty does not allow him to take any more pretentious title than "Königlicher Gartemeister," but whose acuteness and carefulness as a botanist and skill and knowledge in cultural details give him a well-deserved reputation, worth much more than any formal title.

The Forest Academy at Münden was established about twenty-two years ago. It is situated almost in the heart of the little town, which, by the railway, is about half an hour's ride from Cassel, and is in the midst of a region of large areas of forests. Three or four degrees below zero of Fahrenheit is considered very cold here and especially disastrous to vegetation when there is little or no snow on the ground, as occasionally happens, while eighty-five degrees in summer is considered very hot, and is rare. The temperature is greatly modified by the surrounding forests, but early frosts in September and late frosts in May are liable to occur. The grounds of the academy and its connected Botanic Garden only comprise about eighteen acres, which are almost entirely given up to classified collections of hardy plants. The academy buildings are well fitted to answer their purposes, and comprise library, laboratories, lecture-rooms and rooms devoted to specimens, and a collection of tools and appliances relating to arboriculture, forestry and dendrology. The students have the extensive surrounding woods in which to prosecute study and work in practical forestry. It is an excellent station for a school of this kind, because within easy access woods are to be found growing under different conditions of soil and exposure.

It is not my purpose, however, to notice this establishment as a forest-school, but rather to mention a few individuals in the remarkable collection of shrubs which exists here. The limited area of the grounds immediately about the academy does not permit of a great growth of trees nor of the introduction of all the numerous garden forms, but the collection contains typical examples of the various species which have attained a fair size considering the short time since the institution was established. But the same number of years have sufficed for a mature growth of most shrubs, which are largely arranged in botanical order and sequence and afford opportunities for some most interesting studies.

I was much surprised to find here some specimens of rare plants which are not to be seen in collections of much greater fame and endowment, for the whole annual cash appropriation for the maintenance of the Münden garden would hardly pay the salary of one good gardener in America.

Considering the winter temperature it was interesting to note

unexpected indications of hardiness in certain plants, while others, which are considered perfectly hardy in the somewhat colder climate of Boston, are said to be tender here. Undoubtedly, the discrepancies in records of hardiness are largely due to the difference in the heat of the summers and also to the degree of humidity.

The Japanese *Ampelopsis* (*A. tricuspidata*, or *A. Veitchii*, as it is commonly known in nurseries), for instance, is not considered hardy at Münden, while it is now one of the most common and best-known wall-climbers in Boston. It is a fact that seedlings or young plants are liable to have a part of their stems destroyed in winter, but when the plants become well established in well-drained soil there is no further trouble.

Mere hardiness, however, is not the only consideration necessary to the successful growth and naturalization of plants, and this is illustrated by the fact that the Douglas Spruce does not seem to thrive at Münden, although it grows so finely at Berlin and most other places where it has been introduced. Plants twenty years old are still shabby little things a few feet high. Whether this is owing to peculiar conditions of the soil or some such cause is a matter for investigation. But some other Pacific coast or Rocky Mountain conifers do well, for we find here the much more tender *Sequoia gigantea* with a stem over a foot in diameter, Lawson's Cypress twenty-five feet high, and even *Pinus contorta* quite healthy and fifteen feet in height. The Western Hemlock (*Tsuga Mertensiana*) has grown over twenty-five feet, while two Japanese conifers, *Picea Alcoquiana* and *Larix leptolepis*, have made the exceptional growths of over thirty and of forty-five feet respectively. Although the latter bears an abundant crop of cones, it produces no good seed.

Perhaps the very rarest plants in the collection are our *Cercocarpus*, the so-called Mahogany-trees of the western states, both of the United States species being represented. Probably these plants cannot be counted of much ornamental or horticultural value, and perhaps it is for this reason that greater efforts for their successful cultivation have not been made. Nevertheless, they represent a curious and interesting genus in the Rose-family, and on this account one would expect to find them in cultivation in botanic gardens or arboretums. They are, however, generally considered difficult to cultivate. The plants at Münden are the only specimens I ever saw, and it is doubtful if examples exist even in such great collections as there are at Kew. *Cercocarpus ledifolius* has attained a height of eight feet and has flowered, while *C. parvifolius* (*C. betulifolius*, Nuttall) is about seven feet high, and has flowered and fruited, and is considered quite hardy here. On the other hand, *Stuartia Virginica* is not thought hardy, although it lives. Some other American shrubs seem quite at home, and grow with a vigor rarely seen in such species in cultivation. Our little White Mountain Cutler's Willow (*Salix Cutleri*) is thriving well, the extremely rare *Neviusia Alabamensis* is represented by a very good vigorous plant, and the uncommon Colt's-foot (*Galax aphylla*) is better than is usually seen in gardens. The rare *Fendlera rupicola* is here bearing fruit, and a fine large clump of *Itea Virginica* was just (August 18th) going out of bloom.

All accounts describe the little Pale Laurel (*Kalmia glauca*) as being a slender and very straggling shrub. It certainly usually is so in its native swamps, and in cultivation it rarely assumes a very bushy character. That it may be grown in much better form is shown in this garden, where may be seen a splendid compact specimen three feet high and five feet across. This species is so different from the other two (*K. latifolia* and *K. angustifolia*), and it blossoms so much earlier, that it should be better known in all gardens where Heath-plants will grow. The tomentose-leaved *Clethra*, which has often been classed by botanists as merely a southern form of our *C. alnifolia*, was already in bloom. This specimen is ten feet high, and bears the very appropriate name of *C. tomentosa*, by which cultivators distinguish it from the northern smooth-leaved species. It has a peculiar value in its habit of blooming much later than the typical *C. alnifolia*. *Pyrus rivularis*, the Wild Crab of Oregon and that region of our continent, is here about twelve feet in height, and fruiting, while the Pawpaw (*Asimina triloba*) is a bush seven or eight feet in height.

The garden contains a considerable number of interesting Japanese species of woody plants. I was surprised to find *Abelia serrata* counted among the hardy shrubs. Wherever it can be found to endure the winters this should be a desirable plant, on account of its pretty light reddish, sweet-scented flowers and deep green foliage. *Helwingia rusciflora*, also commonly known as *H. Japonica*, is a native of Japan and China rarely seen in cultivation, probably because it has no

known ornamental qualities. But it is interesting as a curiosity, because the very small and inconspicuous flowers are produced on the midribs of the leaves about in the centre of the upper surfaces. The species is dicocious, the staminate and pistillate blossoms being produced on separate plants. The specimen at Münden is three or four feet high and is staminate, and has therefore produced no fruit. This curious shrub has not yet proved hardy at the Arnold Arboretum, but it has flowered, producing staminate blossoms. As there appear to be no records to the contrary, it would seem that the plant has not yet fruited in Europe or America. The fruit is a rather dry little drupe, but it is said that the natives of the mountains of Japan use the young leaves as a vegetable. *Hydrangea scandens* and *Schizophragma hydrangeoides* are two Asiatic plants about which there is often much confusion. The *Schizophragma* has not yet been found very hardy at Münden. In ordering either of these species from nurseries one is liable to get the other. But the *Hydrangea* may always be known by its very few sterile or ray flowers having four large rounded or retuse bracts together and in opposite pairs, while in the *Schizophragma* the leafy bracts are solitary, oval, narrow and somewhat pointed.

Another plant which may be mentioned, because extremely rare in cultivation, is *Eleutherococcus senticosus*, a hardy Araliaceous plant from northern Japan and China, which I found here seven feet high and in fruit; while *Acanthopanax ricinifolia*, a member of the same family, is fifteen feet in height and gives every promise of becoming the large tree with a tropical aspect, which it is said to be in Japan. This species has proved quite hardy at Boston, and it is probably capable of withstanding quite a number of degrees below zero of Fahrenheit.

The species mentioned give but a slight idea of the character of the collection of shrubs and trees under Dr. Zabel's care, and yet the rare herbaceous perennials have not been referred to. The collection contains a very interesting and complete series of species and varieties of *Spiræas*, one of the most distinct of the least known being *S. longigemmis* of Maximowicz. Numerous hybrids of these, and also of Bush Honeysuckles, have been procured and propagated, and from these some improved forms possibly may be introduced to add beauty to our gardens.

Arnold Arboretum.

J. G. Jack.

Plantains.

THE following extract is taken from the last report of the Botanical Garden at Demerara:

The generally accepted opinion of botanists is that the Banana and Plantain are but forms of one species. Yet, from an economic point of view, the two are widely separated, for, in regard to utility as a food-product, the banana cannot be compared with the plantain. Without explaining all the differences, it may be briefly stated that while the banana is a pleasant, agreeable and much-appreciated fruit, it has, judging by the preference of the people of torrid lands, little economic value as a food-product; the plantain, on the other hand, is regarded as intrinsically one of the best natural food-products in the world. Yet the opinion of the botanists is in a way supported by the non-scientific observer, for, except in rare instances, only after long and well-trained field experience can one plant be distinguished from the other when not in flower or fruit. When in fruit, however, the case is different. There is then a character, observable at sight, which only requires to be pointed out for the veriest novice in the subject to be able to tell which is which. In the Banana, after the fruit has set, the succeeding clusters of flowers, often a hundred or more in number, and their large embracing bracts, drop away, leaving a clear, absolutely naked, long extended and still elongating stem or axis, hanging tail-like two to three feet beyond the fruit, with the firmly compacted mass of unopened bracts and flowers, bud-like, at the end; while in the Plantain the stem ceases to extend more than twelve or eighteen inches beyond the fruit, the succeeding clusters of flowers and bracts all opening to the very end, and remaining persistent, withered and dry—the trash as it is called in colonial phraseology—permanently attached to the stem. In the Banana the axis continues to grow as long as the fruit hangs, cluster after cluster of flowers, with their bracts, opening and dropping away, a mass, like an enlarged *Nelumbium*-bud, still unopened, remaining at the far extended end when the bunch is cut; while in the Plantain the growth of the axis is arrested soon after the fruit sets, the abortive flowers opening, and remaining attached, from end to end of the stem. A single exception to the rule obtains in the

case of the Dwarf or Chinese Banana (*Musa Cavendishii*), in which, as in Plantains, the abortive flowers and their bracts are constantly persistent. The texture of the plantain is such that at whatever stage it is used, whether green or ripe, it must be cooked to make it palatable. It is this quality in the plantain which makes the great economic difference between the two fruits. Plantains are chiefly used by the populace while still green—i. e., cut at some period before they are full grown. They are cooked either by boiling or roasting, chiefly the former. To successfully peel a green plantain without soiling it, the operation must be performed with wet hands or with the fruit immersed in water. The plantain contains a measure of tannic acid, and consequently in boiling in a metal pot has a tendency to turn very dark. This may, however, be prevented by boiling a little fat with the fruit—say a bit of fat pork. Green plantains are also used for making soup. For this purpose they are boiled and then pounded in a mortar, when they form a homogeneous mass, like dough, which is put into soup and eaten with it. In the mature, but still green stage, plantains are roasted and eaten with butter, pepper and salt, and in some cases cheese. In this state they are delicious. The plantain parts with its heat very rapidly, and in cooling it loses, to the palate, much of its best taste. It is spoiled by re-warming. For this reason roast plantains are usually served wrapped in a table-napkin, for, to be enjoyed at all, they must be eaten before they cool. When ripe—that is, when the skin has turned yellow—a fruity character is assumed, and then they are used either baked whole in an oven, or cut in slices and fried. Baked ripe plantain has much the taste of baked apple, but with a distinctive flavor, and a much more tenacious nature. Lastly, gathered green, dried and ground or pounded, an excellent meal or flour is produced, which makes delicious custards, puddings, gruel, etc., and is highly palatable and nutritious.

Plantains being the staple food of the Creole population, Plantain cultivation is a firmly established industry. Three or four varieties are grown, one or two of which, however, only on a very small scale. Two color-varieties, presenting hardly any distinction in the character of the fruit, but with the stems and stalks of the leaves blackish in one and green in the other, are most generally grown, and form the bulk of the cultivation. They pass under the names of the Black and White, Common or Cow, and sometimes Maiden Plantain. The others are the Giant, or Horse, and the Barooma, both very large-fruited kinds, the latter of which is not much grown. Plantains give a heavier yield than Bananas from the same land. They delight in the stiff, newly empoldered clay lands of this colony, not objecting to the slightly saline element found where the sea or river has invaded the place periodically at spring-tides while it was lying fallow under the natural bush-growth. Such lands yield heavily, but the crop is liable to suffer, if the seasons for the first two years after planting prove very wet, from the Plantain-disease of the colony. On dry land it does not do much damage. Introduced to such land it soon disappears again. The disease which affects Coconut-trees, from which many are from time to time lost in ill-drained situations, appears to be identically the same. In both cases it takes the form of internal decay, the substance turning to a sodden, offensively scented, putrid mass. The plantains produced by diseased trees are black inside, but not soft like the interior of the stems and root-stocks of the plants. They are, of course, quite unfit for food. Its nature has not yet been determined, though it has been observed closely in the fields, and samples of the affected parts have been examined by distinguished mycologists to ascertain whether or not it be of fungoid origin. The aboriginal Indian inhabitants of the interior do not, as a rule, cultivate this fruit, though they grow here and there in their cassava fields pineapples and a few bananas.

The Forests of Lower California.

ALONG the boundary between Upper and Lower California no forests exist and the variety of trees is very limited. A few miles south of the boundary, on the broad table-lands of auriferous gravel, begins the beautiful Piñon forest, composed mainly of a Nut Pine (*Pinus Parryana*).

These trees only partially shade the ground, forming an open forest, perhaps thirty miles in width in places, and extending from near the boundary line southward along the backbone of the peninsula, with only an occasional break, to the south end of the Sierra San Pedro de Martin. This forest is continuous for nearly fifty miles, the plateau which it covers varying in altitude from 3,500 feet to near 7,000 feet.

The Piñon is a small but very graceful tree, usually under thirty feet in height, with sheaths of short leaves, which densely clothe the tree. In shape it is very symmetrical, especially such young trees as have not been exposed to adverse conditions.

Encircling the meadows at high elevations is found the Bull Pine, or Piños, which J. G. Lemmon calls *Pinus Jeffreyi*, var. *peninsularis* (*Third Report California State Board of Forestry*, 200). It seems to be most abundant on the mountains east of the San Rafael Valley, at an elevation of 4,000 to 6,000 feet, where it attains magnificent proportions. Lemmon describes this tree as varying from medium to large size, 150 to 200 feet tall. The mining camp of Alamo, locally best known as Hanson's ranch, now obtains its main lumber-supply from this region. On the east the descent to the plain of the Colorado desert is very abrupt, and along the precipices overlooking the desert another Piñon Pine (*Pinus monophylla*) maintains a precarious existence.

A greater diversity of forest-vegetation exists on the San Pedro de Martin mountain, the highest mountain in Baja California. Its elevation at the highest point is over 11,000 feet. On this mountain occur the Sugar Pine, Coulter Pine, the White Fir and other trees which here find their most southern station. The summit of the mountain is a world in itself, over fifty miles in length, and was selected as the site of one of the old missions, the ruins of which may yet be distinguished. It is very difficult of access, and as yet has never been visited by a botanist.

The two views published in this issue will be of especial interest as giving a glimpse into an unknown land, and are from photographs taken by Messrs. Roscoe Howard and Russell Gunnis, the first men to invade these sylvan glades with a camera. The Pine in the foreground is Jeffrey's Pine (see page 185). The magnificent proportions of this tree may be realized by a comparison with the man standing beneath it, while the trees around even surpassed it in altitude.

The broad grassy meadows intervening between these patches of woods are still pastured by deer, and game of other descriptions abound. The coyote and the mountain lion are not unknown. The noonday siesta of the rattlesnake is seldom disturbed, while the call of the quail alone breaks the silence of the woods.

To the southward of this mountain an unbroken desert extends for two hundred miles, while desert sands alone intervene between its eastern base and the Gulf of California. Thus San Pedro de Martin furnishes the most southern typical California forest, the forest farther south being composed mainly of cacti and desert vegetation.

C. R. Orcutt.

San Diego, Cal.

Plant Notes.

Some Recent Portraits.

To American readers the most interesting figure in the March issue of the *Botanical Magazine* is that of *Cereus giganteus* (t. 7222), the great Tree Cactus of Arizona and Sonora, but not a native of southern California, as is here stated, whose flowering in England last year Sir Joseph Hooker very properly considers one of the triumphs of horticulture. The plant which flowered at Kew is fourteen feet high and four and a half feet in girth, and was procured from Messrs. A. Blanc & Co., of Philadelphia, whose collection of succulent plants is probably unrivaled in the United States. *C. giganteus* is one of the vegetable marvels of the world, sending up a tall single shaft sometimes sixty feet in height, and sometimes separating near the top into two or more upright branches. It is the tallest, although not the stoutest, of all Cacti, and produces an edible fruit which the Indians of the south-west devour both raw and made into a conserve. Numerous attempts to cultivate this plant have been made since General Emory first gathered the seeds as long ago as 1847, during his military reconnaissance from the Missouri River to San Diego, in California; and although Dr. Engelmann succeeded in germinating the seeds and inducing the young plants to live, they have grown so slowly as to give little promise of ever reaching sufficient size to flower. A peculiarity of the plant not noticed in this description is the wonderful durability of the hard woody skeletons of the stems; these can be found lying about the desert and are used for the rafters of houses and apparently are indestructible by any influence of weather.

In the same issue are figures of *Dianthus callizonus* (t. 7223), a lovely Pink of the calcareous Alps of Transylvania, where it flourishes at an elevation of some seven thousand feet above the sea. It appears to be closely related to *D. alpinus*, and, like that species, has solitary flowers with crenate rose-colored petals with a deep red zone of color at their base speckled with white, although the flowers are larger and the leaves more glaucous than those of that species; *Gongora gratulabunda* (t. 7224), a not very showy or horticulturally interesting Orchid, probably a native of Granada, where it was discovered by Warscewicz, and was first flowered in 1857 by the late Consul Schiller, of Hamburg; *Chrysanthemum rotundifolium* (t. 7255), a handsome Hungarian species, differing from those in general cultivation by its strict rigid habit, acutely angled stem and branches, corymbose many-flowered inflorescence, and broad leaves. It belongs to the section *Pyrethrum* of the genus which includes most of the perennial white-flowered species, although it differs from them in the terete, not ribbed or angled achenes, and in the cupular pappus. It is a low-growing plant in cultivation, rarely exceeding the height of two feet, and in the rockery at Kew flowers freely throughout the summer; *Lysimachia paridiformis* (t. 7256), a native of China, where it was collected by Dr. Henry on the Yang-tse-kiang River in 1889. This is a handsome red-stemmed species with bold leaves, yellow corollas, marked like the calyx with glandular streaks, unequal filaments, monadelphous below, and few-seeded five-valved capsules. It is said to be more closely related to *L. quadrifolia* of the eastern United States than any other described species, although the flowers are much larger than those of the American plant.

New or Little-known Plants.

A New Strain of Roses.

IT now appears that the Rose may be added to the list of plants which may be treated as annuals. Seeds of a variety, under the name *Rosa polyantha remontant*, received from a French seedsman early in the year, were sown January 10th. They germinated rapidly in greenhouse warmth, and, after being pricked out, have been grown in a pan on a shelf in the cool house. They are now small plants, two to three inches high, and every shoot apparently is carrying a bud. The first flowers opened April 9th, just three months from sowing. The flowers are coming in considerable variety, white and pink mostly, single and semi-double, an inch or more in diameter. At present they are charming little plants, with small stems and small light green foliage. With their prolific flowering habit and rapid growth they can scarcely fail to prove useful and attractive garden-plants.

Their precocity is certainly novel and interesting. Some few years since Carnation-growers were much surprised by the introduction of a strain of these flowers which could be had in flower in four or five months from seed, surprise which has given way to satisfaction with the desirable *Marguerites*.

Perhaps, the Rose having developed a precocious habit, we may be favored with even finer forms than *R. polyantha remontant*. It would seem that flowers are being inoculated with some of the rapidity of the age.

London Letter.

HIPPEASTRUMS AT CHELSEA.—The special attraction this month in the nurseries of Messrs. J. Veitch & Sons is the collection of *Hippeastrums*, more popularly known as *Amaryllises*. These plants have been a specialty, almost a monopoly, of the Veitchian firm for the last ten years. They have raised many new varieties, every year producing a crowd of new seedlings, a large proportion of which are so far an advance as to merit certificates from the Royal

Horticultural Society. Several houses and frames are devoted exclusively to these plants at Chelsea, one house, sixty feet long by eighteen feet wide, being entirely filled with the flowering bulbs. These flowers are now rapidly approaching perfection, hundreds of fat succulent scapes bearing clusters of enormous trumpets of the brightest as well as the most delicate hues, and forming a picture which gives a horticulturist peculiar pleasure—a picture

is, at any rate, general. We all get excited over big flowers, from *Rafflesia*, *Aristolochia* and *Victoria* to the big *Chrysanthemums* and *Begonias*. *Hippeastrums* are big by nature, so that the breeder had only to improve them in form and tone down their sometimes harsh colors to ensure success. This has been accomplished, chiefly by Messrs. J. Veitch & Sons and the De Graafs of Leyden, and *Amaryllis* is to-day, in England at any rate, one of the most admired of garden-plants.

CYTISUS SCOPARIUS, var. *ANDREANUS*.—I omitted this plant from those mentioned last week as good for forcing. At Kew there are now in flower some beautiful examples of it. They are standards, having been grafted upon the ordinary *Laburnum*, and each plant has a head a foot through, formed of many long branches, which are clothed for their whole length with beautiful yellow and rich madder-brown flowers. Among the many flowers at Kew at the present time these plants of André's Broom are, I believe, the most admired by visitors. They are grown in pot all the year, plunged in the soil outside during summer, then placed in a cold frame for the winter, and forced into flower in March by the application of a little heat. If your florists have not made the acquaintance of this Broom already, permit me to strongly recommend it as one likely to find universal admiration.

AMORPHOPHALLUS RIVIERI.—This is a small edition of *A. Titanum*, the huge Sumatran Arum flowered at Kew several years ago. The former is represented by two flowering specimens in an intermediate house at Kew, where it grows well, although it is hardy in a sheltered border. It does not often bloom in gardens, being grown rather for its handsome foliage. The inflorescence is a yard high and has a stalk a foot or so long, a trumpet-shaped spathe nine inches across, and a very long erect club-like spadix. Its color is reddish chocolate. Like all Arums, it emits a very penetrating and unpleasant odor for the first day or so after flowering. It is supposed to be a native of China, though nothing definite is known on this point, it having first appeared in the garden of Monsieur Rivier, in Algeria, about twenty years ago.

BEAUMONTIA GRANDIFLORA.—This plant is now in flower in one of the stoves at Kew. It is a splendid stove-climber, and I gave an account of it in *GARDEN AND FOREST* two years ago, when it flowered magnificently in several gardens near London. It has no equal among large white-flowered stove-climbers; its long trumpets of ivory-white flowers, as large as those of *Lilium longiflorum*, being borne in great clusters on the end of almost every one of its numerous short lateral branches. It grows to a large size, and therefore requires plenty of room, both for the roots and stems. In a sunny tropical house, where it can be treated liberally in summer and kept dry at the root in winter, it makes a magnificent display in March or April. It is Indian and Apocynaceous.

CHINESE RHODODENDRONS.—Chinese plants are conspicuous in the conservatory at this time of year. The Moutan *Pæonies* (forced), the Camelias, and various *Rhododendrons*, commonly known as Azaleas, are the glory of the greenhouse in spring. Of course, the two best known of the Chinese *Rhododendrons* are the hardy deciduous *R. Sinensis* (*Azalea mollis*) and the "Indian Azaleas," which are not Indian. Beside these, however, we now know of over sixty species, all natives of China, mostly in the province of Yun-nan. Some of these are in cultivation,

Fig. 28.—*Pinus Jeffreyi*, var. *peninsularis*.—See page 183.

of health, vigor and wealth of bloom; or, in other words, first-rate cultivation. *Hippeastrums* are among the most recent of the triumphs of horticultural skill. From several species with large flowers, but coarse and "unfinished" from the florist's standpoint, a race of plants has been evolved which have all the charm that size, rich and delicate colors and excellence of form give to flowers. The worship of the big for its own sake may be vulgar, but it

is, at any rate, general. We all get excited over big flowers, from *Rafflesia*, *Aristolochia* and *Victoria* to the big *Chrysanthemums* and *Begonias*. *Hippeastrums* are big by nature, so that the breeder had only to improve them in form and tone down their sometimes harsh colors to ensure success. This has been accomplished, chiefly by Messrs. J. Veitch & Sons and the De Graafs of Leyden, and *Amaryllis* is to-day, in England at any rate, one of the most admired of garden-plants.

mostly through the missionary collector Delavay, who sent seeds of them to the Jardin des Plantes in Paris. I have seen the dried specimens of these Yun-nan Rhododendrons, and they look full of promise for the garden. Mr. Hemsley says that, taken as a whole, they are by no means so gorgeously beautiful as the Himalayan species, though many of them are highly ornamental.

A strikingly beautiful Rhododendron from China is *R. Fortunei*, which was introduced by Robert Fortune in 1859. It is perfectly hardy in England, forms a large handsome evergreen shrub, and produces in early summer large trusses of rosy white flowers nearly as large as those of the great *R. Aucklandii*, which it most nearly resembles. It is remarkable, too, in having seven corolla-segments instead of the usual five of the flowers of this genus. *R. rhombicum* is Japanese. It is an interesting plant, deciduous, with rosy purple flowers, and easy to force. It was introduced to St. Petersburg in 1872. We grow it for the greenhouse at Kew. *R. linearefolium*, also Japanese, is an older garden-plant, but as yet very little grown in England, notwithstanding its hardiness here. It makes a fine bush, and is characterized by linear hairy leaves and flowers with long rose-purple segments divided to the base of the corolla.

AZALEA INDICA is now in every greenhouse, and is represented by very numerous magnificent varieties, mostly raised by the Belgian and French horticulturists. It is curious to read in the *Botanical Magazine*, under a figure of this species published eighty years ago, that it was then a "very rare plant, which has been long anxiously sought for by cultivators of curious and scarce exotics. We believe there are not above three or four individuals of it in the country, and of these only that from which our drawing was made has as yet produced any flowers." It is also stated that Kämpfer enumerated twenty-one varieties cultivated in Japan, including white, red, yellow, purple and scarlet, with spots of the most contrary hues. Fortune found every mountain and hill in the central and southern provinces of China covered with Azaleas as abundantly as Heaths occur here. The finest varieties were cultivated in the gardens there; in fact, only the cultivated kinds were worthy of introduction. The Dutch cultivated the Indian Azalea in 1680, but lost it soon after its introduction. The first varieties obtained from China were brought by a sailor and sold to Knight, of King's Road, Chelsea, in 1833. There were five of them, one a double-flowered variety. *Azalea mollis* has been improved by the Belgians, chiefly by Monsieur Louis Van Houtte, who raised numerous varieties with flowers of better substance and more varied colors than any imported. It was in cultivation here in 1824, and then called *R. Sinensis*. Fortune reintroduced it in 1845, when it was rechristened *Azalea mollis*.

The Best Garden Strawberries.

SHOWINESS rather than flavor has long been the end to which the originators of new varieties of strawberries have generally aimed. As is natural, they have had in view the needs of the market gardener, who is a large purchaser of plants, rather than the requirements of those who plant for home use. Therefore, an early, large, firm, showy, prolific berry has been the ideal one, with little regard to its table qualities. The chance that the best-flavored berry will possess one of these qualities in a marked degree is small. That it should possess enough of them to attract the large grower is improbable. So it is pretty much a matter of luck that we have really a first-rate berry at all.

The best berry that I have tested is the old Crystal City. In exquisiteness of flavor it is unrivaled and matches the best type of wild berry. Then its brilliant, glossy, crimson color makes it an ornament to any table. It is also an extremely early fruit, and for the first few days a very large one. But, while the excellence of color and flavor is retained, the berries soon run small and ill-shaped. Nor is it on the whole pro-

lific; still with those who value quality first, it is well worth raising.

The mammoth size of the Sharpless has won for it a higher place than it deserves, for it is the most deficient in the highest qualities of the strawberry. The color is almost always dull and unattractive, while the flavor is insipid. Nor is it so productive on most soils as other kinds that surpass it in everything except size. The Cloud has nearly all the qualities of a good table berry, except beauty. It is too dull and coarse-looking. The ideal strawberry must adorn a table as a bouquet adorns it. If the strawberry were deprived of its beauty it would hardly rank as it does as the first of fruits. The Cloud is medium early, ripening about with Crescent. The Henderson, which ripens somewhat earlier, is an equally good fruit and more attractive in appearance. All of the very early berries that I have tried, except Crystal City, are deficient in real merit. The Crescent, if allowed to get thoroughly ripe, is surpassed by few among the medium early varieties. Then, too, its wonderful productiveness will help to atone for its shortcomings in the way of flavor. No other variety approaches it in yield. Thrushes and cat-birds, connoisseurs in fruit, prefer the Haverland.

It is only when we come to the later varieties that we find in the Bubach an approach to the ideal berry. Neither in color, size, quality nor productiveness does it leave anything to be desired. On rich soil it will ripen within a week of any other good variety, and in view of its great merit no one will begrudge it these few days of grace. In beauty, both of foliage and of berry, it is unapproachable. A bed of this variety, with leaves of richest green, among which the berries fairly glow, is as beautiful as any bed of flowers. Though somewhat late, the bearing period of the Bubach is correspondingly prolonged, so that berries can be gathered for fully as long a period as from any other variety. Another quality of the Bubach, which should recommend it to the amateur, is that it puts out but few runners even on rich soil. Runners, when neglected and allowed to cover a bed, have been the undoing of many a sanguine gardener. Judging by the appearance of the bed while leafless in the early spring, he hesitates to attack it with trowel or hoe, and he discovers when too late that it has become a jungle of foliage with a scanty show of fruit. As early as possible in spring—the autumn before would be better still—the bed should be thinned out remorselessly till no two plants stand less than six inches apart. The Bubach on good soil makes runners enough, but will give less trouble in this respect than almost any other kind. As it is a pistillate variety it should be planted with some staminate kind like Sharpless or any other blooming about the same time. The Cloud and Crescent are also pistillate, as indeed are most of the best Strawberries. Crystal City being staminate will grow alone. Staminate plants, however, are by no means indispensable, especially on rich soil; but as they increase the yield and quality of the crop, they should be planted with the pistillate varieties when possible.

What was said about the Crescent may be repeated about strawberries in general—let them get ripe. Rarely, indeed, are they allowed to attain this perfect state. We are so eager after the long winter-waiting, and they look so inviting, that at the first gleam of color off the berry comes. But the strawberry is not really at its best till some days after turning perfectly red; nor is it really wholesome till then. Leave a corner of the bed until the fruit thoroughly ripens, and you will thoroughly enjoy strawberries for the first time.

O. W. Blacknall.

Phajus grandifolius in a Window-garden.

WHEN, on the 20th of last February, Mr. John Saul, of Washington, sent me a piece of *Phajus grandifolius* from his Orchid-house, I called to mind the princely gift of an elephant which so embarrassed its poor recipient. To introduce this royal plant into my modest window-garden after it had been accustomed to careful nursing in the atmosphere of a hot-house, seemed very much like turning the elephant out to graze with a flock of sheep on a Scottish down. Nevertheless I determined to give it a chance. Fortunately, it was already well advanced, having four large healthy leaves and a short flower-stalk crowned with a bud, mysterious enough to us who have had little close acquaintance with Orchids, excepting a few hardy, small-flowered kinds. We could not guess what manner of surprise that close-shut bud might contain, but had little hope that it would ever condescend to reveal its secret in our sitting-room.

We did the best we could for our guest, potting it at once in fibrous loam, rich compost and the sphagnum which was

wrapped carefully around it when it came. The thermometer registered five degrees, Fahrenheit, that morning, but the box of tender plants arrived in perfect condition, many of them blooming, with earth around their roots and a coat of sphagnum and another of paper over that to keep them warm and snug, a fact which shows the ease with which tender plants can be sent long distances in cold weather if they are properly packed.

When we had potted the Phajus we searched the indexes of GARDEN AND FOREST and learned, among other things, that a refractory Phajus of another species had been induced to bloom by putting it in the very warmest spot in the hot-house and watering it freely. We took the hint, and watered our treasure twice a day with warm water, placing it as near to the base-burner, which heats our sitting-room, as possible. On cold nights we put the pot on the mantel-shelf, and we sprinkled it overhead with tepid water every day.

Under this treatment we soon found that the stem was stretching out. Up and up it climbed until it caught up to, and then towered above a fine Amaryllis in the same window which has a southern exposure. When it was three feet in height it stopped ascending, and the bud began to swell, but

Flower Notes.

STANDARD ROSES.—These are rarely, if ever, grown outdoors in this country, owing to the fact that the strong summer sun burns the bark of the *R. canina* stock, the only one used for standards. These are, nevertheless, very useful when grown in pots for piazza decoration in early summer. As we need to have ours in bloom by the middle of May, they are taken indoors toward the end of March, pruned and top-dressed with rotted cow-manure. If they have good healthy heads more shoots will be made than will carry good flowers, and so a little disbudding is advantageous. After blooming they are pruned back a little, some soil is taken out of the pots, and replaced by good fresh loam, cotton cloth is wound round the stems to protect the bark from the hot sun, and the pots are plunged out-of-doors for the plants to make their season's growth, when, after ripening with frost, they are placed in the cellar for the winter. Whether *Rosa multiflora*, the new stock (from Japan) which Mr. Jackson Dawson is experimenting with, will ever develop stems suitable for standards, is a question of time. For dwarfs I think it is destined to supersede the Manetti and Dog Rose stocks, owing to its hardiness and superior vigor.

Fig. 29.—A Pine Forest in Lower California.—See page 183.

so slowly that we could not be quite sure that it was really not standing still. In another week the bud separated into seven, and we watched it with increasing interest. At last the lowest bud changed its position from perpendicular to horizontal, and on the 4th of April it had become an exquisite flower, and greeted us with that wide-eyed look which makes one feel as if flowers could see.

Now, on the 12th of April, there are five of its curious blossoms to look at and to wonder over, with two others soon to expand. The plant is remarkably graceful, with its wing-like fresh green leaves, and the quaintly beautiful blossoms mingling sad shades of light chocolate, reddish purple and cream, so blended as to form an exquisite combination. The striped lip is a striking feature, and the silvery lining of the sepals and petals has a rich tender bloom.

Having succeeded so well with Phajus grandifolius, we are impatient for fresh worlds to conquer, and would be glad to know whether other amateurs have attempted to raise Orchids in window-gardens, and what varieties are best adapted for this purpose.

Rose Brake, West Va.

Danske Dandridge.

Imported Roses are very unsatisfactory, because, for perfect satisfaction, there must be thorough acclimatization of both stock and cion. Mr. Dawson's stocks were American-raised seedlings of one year old, and, although they had only been grafted six weeks at the time of my visit, they had made remarkably rapid and substantial growth, and many were already in bloom.

MICHAUXIA CAMPANULOIDES.—I was pleased to see plants of this rare campanulaceous species looking fresh and sound after the winter. By some oversight this had not been protected by the usual covering of Pine-needles. The discovery of its hardiness was particularly interesting to me, as it is one of the things which are considered tender and very difficult to winter in England. A dry, warm, sunny position is generally recommended for it, but where it grew was neither dry nor warm, but the reverse. It is a biennial, and makes a large rosette of Dandelion-like leaves the first season from seed, and forms a Turnip-like root. The following season very rapid growth is made, and if vigorous it will produce an immense spike of white flowers, slightly tinged with pink, which rivals in stateliness the well-known *Yucca angustifolia*. Seeds should

be sown in early spring in the greenhouse. The seeds are so small, and the seedlings so delicate for a long time after germination, that it is almost useless to sow them in the open border. Years ago I grew some fine specimens of this plant in pots, but, although I was thus able to keep the roots dry and cool, I yet failed to save over thirty per cent. of them through the winter. If I have the good fortune to try them again in pots, I shall let them freeze.

LENTEN ROSES.—These plants, mostly hybrids of *Helleborus Colchicus*, *H. guttatus*, *H. Olympicus*, *H. purpureus*, *H. orientalis* and others, of which the varieties *Irene Heine*, *Hofgarten*, *Inspector Hartweg* and *Willy Schmidt* are representatives, are now in bloom. They are very hardy and desirable plants, and some are really beautiful, many of the hybrids being far superior to the types in distinct and bright coloring. In this country they take the place of the Christmas Rose, which, however beautiful, is unsatisfactory, since its natural blooming season is at a time when our winters are too severe to allow of anything in the shape of active vegetation to flourish; and, on the other hand, the summers are too hot. The raising of hybrid Lenten Roses is slow, but very interesting work. The seeds are very slow to germinate. A year ago last August I sowed a lot in a box, and expected to see them come up last spring. Out of five hundred seeds sown only twelve germinated; but this year, I think, nearly all the others must have started, as the box is quite full.

The best plants I have seen were grown under Quince-bushes, which seemed to give them just shade enough.

Wellesley, Mass.

T. D. H.

Narcissus Bulbocodium.

IT is a matter of surprise that this *Narcissus*, the Hooped Petticoat Daffodil, is not more generally known and cultivated by those who grow bulbous winter-flowering plants; while many others are grown in immense quantity, these little gems are seldom seen. When trying to obtain some bulbs last fall I was told they could not be found to the number required in any of three large cities, and they had to be imported before an order for 500 could be filled. No bulb gives more flowers in proportion to its size, as it is quite common to see five flowers to a bulb, so that when planted thickly in shallow pans the effect is very pleasing. It is possible that many have failed with this *Narcissus* because of attempts to force it. Under this treatment nothing but leaves will be produced, as is the case with the *Snowdrop* or *Crocus*. After being potted they should be wintered in a cold frame until the end of February, when the flowers will be produced with very little heat in a greenhouse or in a sitting-room window. *N. Bulbocodium* is of a bright yellow in the typical plant, but there is a variety known as *Citrinus* that has flowers of a lovely lemon-yellow, but this form cannot yet be obtained in quantity at reasonable prices. This last remark applies also to *N. cyclamineus*, the *Cyclamen*-flowered *Narcissus*, which to me is the prettiest of the whole genus. Its dainty and quaint appearance, so different from all others, makes one wish it would live longer in cultivation, but complaints are common that after once flowering it dwindles away, and such has been my experience. Mr. Barr, the *Narcissus* specialist, tells us it needs a moist situation when planted out; but, then, a New England winter is vastly different from that of Portugal, and planting outdoors here is not to be thought of. This kind was lost to cultivation for over one hundred years, owing possibly to the difficulty in growing it, and now that it is rediscovered there is a danger of its being exterminated by collectors unless better success is obtained with it under cultivation.

South Lancaster, Mass.

O. O.

Permanent Narcissus Beds.

AFTER *Narcissi*, and the same may be said of other bulbous plants of this class, have done flowering they should not be disturbed until the leaves ripen. A good way to treat beds in which *Narcissi* have been planted, say from a foot to eighteen inches apart, is to sow the seed of *Mignonette* between the rows, which will about cover the ground by the time the foliage of the *Narcissi* has died, or, at least, has so far ripened that it will sustain no injury from the *Mignonette*. After the first frosts in fall the *Mignonette* may be removed from the bed and a good top-dressing of well-decomposed manure given. The fall rains will wash the plant-food down to the roots of the bulbs, which are in need of just such encouragement to enable them to start again and flower the next year better than before. Many other tender annuals might with advantage be used in this same manner, and a permanent

bed of *Narcissi* can be had which will yield from year to year an abundance of flowers bright and fresh without any forcing-house feebleness. Then, too, the bulbs need not be thrown away after flowering, but they can be left in the ground to increase and produce double the quantity of bloom the next season. After the third year they should be lifted, separated and replanted. When the soil is a heavy tenacious clay the bulbs will be better if lifted every second year. The reason for this is that as the bulbs expand their growth is more or less hindered by the resistance made by the soil against which they press. If we lift a clump of any strong-growing *Narcissus* the third year from planting in a heavy soil, it will be found a compact mass of bulbs, small and imperfectly developed for want of space. These would hardly be able to flower another season; perhaps they would not flower well the third year even. Where the soil is light the bulbs meet less resistance, and they will be larger and stronger.

One who buys imported bulbs of *Narcissi*, such as *Sir Watkin* or *Bicolor Horsfieldi*, is at once struck with the difference between these and home-grown bulbs of the same varieties. The foreign bulbs have much shorter necks because of shallow planting, while home-grown bulbs have long necks, and present a very different appearance. Home-grown bulbs planted in August will prove far superior to imported ones in quality and abundance of bloom. There is a wide difference of opinion in Europe as to the best depth and time to plant. Our climate certainly calls for deep planting to guard against the action of frost, which may force the bulbs out of the soil and otherwise injure them. The lifting may safely be done as soon as the foliage begins to turn yellow. Roots will be found adhering to the bulb, but their work is done, and they are useless. It is good practice to reset the bulbs as soon as possible.

South Lancaster, Mass.

O.

Growing Plants in Moss.—Sphagnum has some advantages over soil, as a medium for the roots of plants, especially where it is desirable to have them in boxes or stands, and more particularly under the shade of trees, which, like the *Silver Maple*, are always ready to throw out their feeders and appropriate all the plant-food within reach. There are many plants which will thrive and make a good display all summer in such situations if they can be protected from the encroachments of the tree-roots, and this can readily be accomplished by growing them in boxes, which may be either placed on the ground or elevated by means of rustic supports, as taste may dictate. One of the most satisfactory flowering plants for such a position is the *Fuchsia*, and many plants with ornamental foliage do well. These boxes need not be over three or four inches deep, and in filling them I generally put in about an inch of soil first, although this is not absolutely necessary. I then fill in the moss in layers, with a good sprinkling of hen-manure or other good fertilizer between the layers, and, if the box is shallow, carry the moss somewhat higher than the sides and round it up in the centre. The plants are then dumped out of pots and the balls of earth well covered in the moss. Some of the advantages in using sphagnum are its readiness to take up and retain water, it does not crust over, and its porous nature admits air so freely that there is very little danger of injury by overwatering. Sphagnum is now offered by several firms in various parts of the country at low prices by the barrel, and those who cannot have ready access to swamps that produce it can easily procure it.

Hampton, N. Y.

Wm. F. Bassett.

Papyrus Antiquorum, the Egyptian Paper-plant, as it is often called, has long been prized as an aquatic plant, and when associated in the water-garden with the so-called *Lotus* (*Nelumbium speciosum*) it can hardly be excelled in gracefulness. As a general decorative plant for the conservatory and dwelling-house it is rarely met with, but it is equally adapted to this purpose, and good plants can be produced in eight or ten inch pots. Large specimen plants require to be grown in watertight tubs, and when used as the centre or as a background for groups and masses of plants it becomes a conspicuous object, towering ten to twelve feet high, with plumes two feet in diameter. As a pot-plant it is as readily grown as *Cyperus alternifolius*, and requires the same treatment, but being much stronger, it is not adapted to such small pots as the *Cyperus*. The soil should be good turfy loam, enriched with thoroughly rotted stable-manure. With the same soil in tubs without drainage it can be readily grown into large specimen clumps by using several pieces in one tub. When growing freely the tub should be occasionally filled up with liquid manure. General greenhouse temperature and treatment suits it admirably. As a summer decorative plant for the mixed border, or

in groups of sub-tropical plants, it succeeds well under the same treatment as Cannas, but for a specimen clump several pieces, according to size, should be set in half a kerosene-barrel, as recommended for conservatory specimens. The half barrel should be sunk until the rim is at the level of the ground and practically out of sight. With applications of liquid manure in hot and dry weather the clump will make an astonishing growth. The plants should not be allowed to suffer from high winds and storms, and a few neat stakes can be used, or other means of protection and support should be supplied. In the open ground this Papyrus is not inclined to grow so tall or make such rapid growth, but the stems will be stronger and will not need so much protection as the larger plants. Papyrus Antiquorum is propagated by divisions of the roots and by seed, but strong plants only produce seed to any extent. Seedlings raised early in the season make nice plants the first summer; strong clumps the second season.

Begonia Triomphe de Lemoine.—Plants of this variety were grown in the open border last summer with great benefit to the foliage and much better results in the way of flowers. For profuse and lasting flowers this variety probably heads the list of Begonias. The plants are fairly covered, as they have been for months, with masses of bright flowers, which scarcely even yet show signs of fading. The color is a bright light red, almost pink. A good stock of this plant in small sizes is very useful and attractive in the greenhouse in winter for decoration of the benches.

Corydalis bulbosa (or *C. solida*), the purple Fumitory, is a neat little bulbous plant now in flower. The leaves are attractive, and the effect is somewhat like that of a small Dientra, the plant being only a few inches high, with numerous purplish red flowers, not especially attractive except as a patch of color in a dull season, when all color is welcome. The bulbs are hardy, and rapidly increase from offsets. There is also a white variety of this species, but this has not been grown by me.

Elizabeth, N. J.

Correspondence.

The Northern Limit of Sabal Palmetto.

To the Editor of GARDEN AND FOREST:

Sir,—Jutting out into the ocean at the mouth of the Cape Fear River, thirty miles below Wilmington, North Carolina, is the delta-like formation known as Smith's Island. Formerly the river had two mouths, one opening eastward at the north end of this island, and the other running out to the south. For the improvement of the entrance the mouth at the north end of Smith's Island has been closed by a stone dam nearly a mile long, connecting the island with the beach at Fort Fisher, of historic fame. This work has caused the current to scour out the southern channel until the river is now navigable by large ocean steamers, and its depth is still increasing. Having often heard of the sub-tropical character of the forest upon Smith's Island, I was glad to embrace the opportunity to visit it in company with Professor Holmes, State Geologist, and Mr. T. K. Bruner, Secretary of the State Board of Agriculture. Professor Holmes wished to study the geological character of the island, and Mr. Bruner and I had in view the lifting and preparation for removal to Chicago next spring of some specimens of the native plants, particularly the Palmetto.

Our course to the island was by Wilmington, and thence by steamer to Southport, the pretty pilot-town near the mouth of the river, from whence we reached the island in open boat. Southport occupies an elevated plateau on the right bank of the river, and its twelve hundred inhabitants are now stirred up with the idea of getting railroad communication to the Virginia coal-fields and making their beautiful village a great coaling-station. At present it is unspoiled. The streets are broad and clean, and all about, even in the middle of the streets, magnificent widespreading Live Oaks have been left, which add a peculiar charm to the place. In the cottage-yards native plants are not neglected, and I found beautiful specimens of the *Ilex vomitoria*, the North Carolina Tea, densely packed with its brilliant red berries, looking like glass beads from their translucent character. In one yard stood an Orange-tree, with leaves only slightly yellowed, testifying to the mildness of the locality. Phlox Drummondii, Verbenas, Sweet Alyssum, Violets and many other plants were blooming, as many of them had been all winter. Though an easterly gale was blowing, our boatman decided that we could cross to the island, four miles away, which we swiftly did, and landed in a quiet creek near the Bald Head Lighthouse. The island is

about six miles long and four wide. Its only inhabitants are the lighthouse-keepers at one end and the life-saving crew at the other. The larger part, and, in fact, all the upland part, is covered by the densest forest-growth imaginable, so dense, indeed, that it can only be penetrated by cutting paths with an axe. It is literally a forest of evergreens. Hardly any deciduous trees are found, and few deciduous shrubs. The principal forest-growth is *Ilex vomitoria*, which forms impenetrable thickets, Holly, Live Oak, Water Oak, Red Cedar, *Osmanthus Americana*, Pinus Taeda, called here Rosemary Pine, and lastly, but not least, Sabal Palmetto. Sabal Adansonii is plentiful on the mainland far north and east of Wilmington, but we found none of this dwarf plant here.

The magnificent growth of Sabal Palmetto here in what seems to be nothing but pure sand and shell fragments surprised me. We found plenty of trees with tall columnar stems thirty feet tall to the crown of leaves, and an immense multitude of young ones. I cut and brought home with me single leaves which measure five feet from base to apex, seven feet broad, with petioles six feet long. This shows that, although the tree does not range farther north, for none are found in the forest on the mainland north of the Cape Fear River, it nevertheless reaches its full development on the island. The forest is inhabited by countless numbers of raccoons, a great many wild hogs and feathered game, both land and water fowl, while the waters abound in fish, oysters and clams. We selected some grand Palmetto-stems for our forestry exhibit at Chicago, and made arrangements to have a large number of moderate size carefully lifted and planted in large boxes, which will be plunged at once where they grow, in hopes of getting a fair number established so that they can be transported to Chicago next spring to plant around the North Carolina building. Specimens of the *Ilex vomitoria* and *Osmanthus* will be treated in the same way. In the high mountains of the west we are also lifting the Balsam Fir and other plants of that locality, so that we can illustrate the wide range of climate in the state with plants of the climate of Canada and of the Mexican Gulf side by side.

The size of the Live Oaks on this island is surprising when the character of the soil is considered. We bored seven feet in the soil near Live Oaks four feet in diameter, and found only sand and shell fragments. Over the tops of the tallest trees the Smilax, probably *S. laurifolia*, made a cover as dense as Ivy, and in all the hollows back of the sand-dunes *Mitchella repens* made a thick soft carpet. On the beach Sea Kale (*Cakile*) was in bloom, and furnished an acceptable dish to the lonely dwellers at the lighthouse.

W. F. Massey.

A Plea for Warm Tints in House-painting.

To the Editor of GARDEN AND FOREST:

Sir,—I have read with much interest the article on "Color in Rural Buildings," in your issue of March 30th, and while deferring to your contributor's well-known judgment in matters of taste, I would like to say a word on the side of those deeper and warmer colors in houses which she finds less well adapted to our atmospheric conditions than the whites, pale yellows and grays, to which she gives the preference, and at the same time to ask for some suggestion about the proper colors for villages.

Mr. Downing's rule for painting was to turn over a clod and paint the buildings the color of the soil disclosed, which he esteemed a method likely to bring the house into harmony with the surrounding earth. The color of the soil when wet would yield one tint, when dry another.

This rule, of course, if applied to a village, would produce monotony; but it was intended more especially to refer to the treatment of isolated country houses, which might be expected to rise from foundations widely different in hue, according to the geological formation of the region in which they were built. This method accounts for the unobtrusive and rather dingy shades which were employed in his time, which had, at least, the merit of not particularly forcing mistakes of construction upon the attention, and kept the building subordinate to the landscape. But, to my mind, the chief difficulty in painting a northern country house is that it must be adapted to two seasons, and, consequently, must hold its proper place in two widely differing color schemes.

In New England, for instance, for nearly eight months out of the twelve, every country house stands in a landscape from which all green but that of conifers has disappeared. It matters little of what hue a building is, when it has the vivid contrast of foliage to help it out, the soft dappling of leaf shadows upon its surface cast by surrounding trees, the relief of turf

and climbing vines about its foundations, and the sunny beauty of a summer sky behind. It is thus that the occupant of cities pictures a country house, it is thus that he sees it, and to this surrounding all mere summer cottages and houses may wisely be adapted.

But your true dweller in the country is faced by a different problem, having, unless his home stands in a bower of evergreens, to see it most of the time bare against a dull and lowering sky, with tall gray trunks of trees and a network of dark branches in relief against its surface, and frequently a snowy foundation and roof, to try its complexion still further. When the short and chilly days come, white and cold-colored houses have a shivery air, like lasses clad in summer gowns in a snow-storm. The green blinds make black spots against the prevailing whiteness, and the whole effect is apt to be disconsolate. Under these conditions a little red farm-house or school-house gives one a sense of satisfaction, of warmth and comfort, which shows that, after all, a dash of vigorous color does not come amiss in a New England prospect, which is sombre, if not dreary, for nearly three-quarters of the year.

Probably it was not aesthetics that our forefathers considered in their choice of colors, but economy, yellow ochre being the most enduring of colors, and white being the only pigment that permits refreshment of a building in the stained and disfigured portions, without making painting the whole a necessity. But it is one thing to have a white house in the south, surrounded by Oleanders and Camellias, with Palms and Eucalyptus to fleck it with shadows even on winter days, and another to see a house of this color staring bleak and cold under the shadeless gloom of a New England January.

The south of France and Italy show masses of foliage all winter long. The Live Oaks cast their dense shade, the glossy Camellias form clumps of verdure, Cyresses and Stone Pines are everywhere, the Eucalyptus is green in December; there are leafy hedges in the gardens always. In February the ground is dappled with Anemones and Violets. Winter there is but a nap of the blooming earth, not the syncope of the north, which sometimes almost makes one doubt whether the spring will ever come again, to loosen the cold slumberer from the iron bands in which the winter has bound her. Therefore, though our sun shines, and our skies are of pale blue, the conditions are widely different, and those gayly painted and frescoed exteriors, so amusing and pleasing amid the smiling winter surroundings of the Riviera, would seem as strangely amiss against our solemn Firs, and funereal Junipers, as a Puritan in motley.

For the same reason it seems to me that while light tints are agreeable in isolated summer houses, a country town must needs have more variety and warmth of color for those houses which are to be occupied at all seasons, and that there are many places where something warm and solid composes with the surroundings better than a light tint. The superiority of stained shingles over painted clapboards comes from the fact that the color surface is broken as it is in nature, and there are no broad stretches of one unvarying tint, which is of necessity inartistic. Stone and brick, plaster and unpainted wood take on a variety of shades that break up monotony, and unconsciously give satisfaction to the eye, which wearies of sameness; but neither stone nor brick nor plaster makes desirable country houses for all-the-year-round occupation in New England, for they gather dampness, and require artificial heat to keep them dry, except in the very middle of our short summer. Hence we are forced to the consideration of some artistic variety in the treatment, not only of wooden dwellings surrounded by grounds, but also of villages of frame-houses, which are even harder to manage, since one's neighbor's idea of color may be in direct conflict with one's own, or, what is perhaps even more trying, one may promptly find his carefully selected hue reproduced on a dozen different buildings, to which it may be inappropriate.

It is possible that in future days villages may be painted artistically to order, by contract, in sections that agreeably harmonize with each other, while affording some variety of general effect. At present the variations on the original yellow theme of colonial houses have reached a maddening variety, scaling from orange to straw color, with such intermediate shades of banana, and chrome, and lemon-yellow as happen to appeal to the proprietor's more or less educated eye.

This phase, too, is passing, but its succeeding fashion will also pass, and thus forever the old order changes, giving place to new, and while we are grateful to the wise ones who shed light upon our darkness, we mistrust the infallibility of any rule or any fashion as applicable to all situations, and all seasons, and seek for more light upon this difficult subject, which shows the same complications as the effort to make a

house serve with equal comfort as a winter and a summer dwelling.

Hingham, Mass.

M. C. Robbins.

Sweet Peas

To the Editor of GARDEN AND FOREST:

Sir,—Is it too late to plant Sweet Peas?

Albany, N. Y.

R. A.

[It is not too late in the latitude of Albany, but, as a rule, the earlier Sweet Peas can be put in the ground the more vigorous will be the plants. They should be planted just as soon as the ground can be worked in spring, and there need be no fear of injury from frost. The ground should be worked deep, say eighteen inches or even two feet, and fairly good garden-soil will give an abundant yield. It is well to plant thinly in a furrow some five or six inches deep, covering the peas with about three inches of soil and drawing the earth up to the plants as they grow until the bed is level. Give them tall brush or a wide trellis of wire-fencing to run upon and cut the flowers every day, and they will keep on blooming until frost.—Ed.]

Sand Dunes.

To the Editor of GARDEN AND FOREST:

Sir,—I should like to offer a plan for protecting water-fronts from shifting sand that suggested itself to me while examining a harbor on Lake Michigan.

In GARDEN AND FOREST (vol. iv., p. 503) Mr. J. B. Harrison speaks of the necessity of beginning near the water's edge. There may in places, however, be serious objections to planting the outer row of Cedar-saplings suggested by him. A quicker and cheaper plan would consist in driving sharpened boards, six or eight inches wide, and, according to circumstances, from three to six feet long, into the sand in a continuous row, thus making an obstruction that would catch the moving sand in drifts. As these boards become uncovered they could be driven deeper, and if buried could be raised by hand. In this way enough protection would be given that the spontaneous growths would be given an opportunity to gain strength, and it would be easy to make the shelter permanent by planting a close shelter belt behind this fence, if I may so call it. On the Lake Michigan shore the best deciduous tree would be the Balm of Gilead; it thrives well on exposed sandy shores, and could be cheaply propagated from ripe wood driven into the sand. The proper evergreens to plant with it are the White Cedar and the White Pine, the former for a permanent low screen, and the latter to eventually succeed the Balm of Gilead.

It can readily be seen that a screen of this character would cost very little. A couple of men could cut down Balm of Gilead or similar trees and cut them up into cuttings two or three feet long, and plant these very quickly. It would require about sixty-five feet of cull lumber per rod of fence. This lumber would cost, hereabout, not over forty cents. It would be interesting to know what it would cost to protect a mile of shore-front, and, if it has been tried anywhere, readers of GARDEN AND FOREST would like to hear the result.

Milwaukee, Wis.

Charles L. Mann.

The subject of the fixation and reclamation of sand-dunes is one which has attracted the attention of engineers in the Old World for years, and a large literature and record of experience exist; but of valuable works on the subject I know but one, the classic treatise of Joseph Wessely, *Der Europäische Flugsand und seine Kultur* (The European Shifting Sands and their Cultivation), Vienna, 1873, which, while treating the subject with special reference to local conditions in the desert of Hungary, yet enlarges upon the principles which rule everywhere, and should be in the hands of any one attempting the solution of such problems.

The difference between the shifting sands of the interior and those of the seashore is, that in the first case a great mass of sand is in question, which once fixed is fixed forever; while in the latter case the sea is constantly bringing up new material, and hence the work of fixation is never entirely done, and requires more or less constant watching and renewal. Mechanical works, such as fences, covering with brush, straw, turf, will be less effective and less per-

manent than a fixation by means of a plant-cover, the root-system of which penetrating in all directions will bind the sand as no mechanical appliance can.

To establish a plant-cover, however, it may be necessary to quiet the sand first temporarily, and to some extent artificially, before the planting is begun. The necessity for this and the means and methods will differ according to local conditions.

When dealing with sand-dunes at the seashore it is necessary to first cut off to some extent the supply of sand constantly brought from the sea. This is done by raising the shore or front with a tolerably steep grade, which, while having slope enough not to be endangered by underwashing, forces the waves to carry back the sand they bring up. This is most simply done by establishing an artificial front or forward dune. This forward dune is formed by running two parallel fences along the shore, made of brushwood hedge fashion, six feet apart, and so high that the top of each may be, say, eight to ten feet above average water-level. These hedges are braced up if necessary by post and rail, and are expected during the summer to catch the shifting sand between, in front and rear, and thus to form the forward dune.

Should this dune not be high enough to keep off the sea winds and their effects upon the sand masses beyond, especially if these are extensive, a second dune, the so-called "high dune," established in a similar manner, only higher and parallel with and behind the first, becomes necessary. To make the dune effective against the sand which is constantly added to it Sand-grasses are planted, which, as the sand covers them, grow through it to the surface, and keep the dune permanently in proper condition. The best grass for the purpose has been found to be *Ammophila arenaria*, which is easily and successfully transplanted. This grass is native along the Atlantic coast and the lakes, as well as in Europe. It has been used, I understand, to bind the sand of the Golden Gate Park, San Francisco.

When the shifting sand has been quieted, reforestation can be resorted to to keep it permanently and securely in place. For this purpose the Pine tribe furnishes, probably, most desirable material, although other kinds will grow where a fresh subsoil is present, especially Poplars and Cottonwoods, and some Willows, which are most easily propagated by cuttings. The choice of material might be indicated by the surrounding flora. Brush Willows and any other low shrubs have been found objectionable because they induce the formation of hillocks around them.

Above all, the dune must be constantly watched, and any small damage repaired at once, since small defects are very rapidly enlarged, and prompt action can prevent this.

The Study of Leaves. By Mary B. Dennis. D. Appleton & Co.

This little handbook is not an exhaustive treatise in which everything that is known about leaves is set forth in due order, but it is intended simply to help and encourage the acquiring of habits of observation by the young—that is, it does not attempt to tell children what other people have discovered, but it directs their attention to the proper way of finding out things for themselves. Very little, therefore, is said in the book about the physiological functions of leaves or their chemical constitution, as the primary purpose in view is to direct children how to look at leaves so as to describe and identify them. To this end there are something like a hundred blank schedules for leaf-analysis. The child is instructed that it is not necessary to know the name of a plant before its leaf can be analyzed, but that the first thing to do is to become familiar with its appearance. The first title in the schedule is "Arrangement." In one of the few preliminary pages it has been explained what the terms opposite, alternate, radical, whorl and fascicled mean, and there are excellent outline sketches to illustrate the explanations. What the child has to do then is to examine the leaf and write in the schedule the proper descriptive term for its arrangement. The leaf is studied in the same

way with reference to all the various items in the schedule, such as its venation, margin, surface and the rest, and when this has been done and the results recorded the student must have obtained a pretty distinct idea of the external appearance of the specimen. Besides this there are some short directions for pressing leaves, for drawing them, for painting them, and printing them and skeletonizing them. Altogether the little book can be thoroughly commended to parents and teachers, and the child who begins the study of leaves in accordance with these directions, and pursues it with ordinary diligence during the coming season, will have acquired not only some knowledge, but what is much better, the habit of getting knowledge which will be retained through life.

The Plant World; its Past, Present and Future: An Introduction to the Study of Botany. By George Masee. New York, Macmillan & Co.

The author of this little book is the lecturer on botany to the London Society for the Extension of University Teaching, and it is another of the numerous attempts to furnish instruction to everybody in all branches of science. It contains seven chapters, the first of which is entitled Plant Architecture, and attempts to give the various uses of the different organs of plants, the modifications of these organs caused by external agencies and their microscopic structure. Then follows a chapter on the chemistry and physics of plant-life, and another on the arrangements for protecting various plants against climate, living enemies and waste of energy in the struggle for existence. A treatise on the reproduction of plants follows this, and then comes a chapter on the relationships of plants, which includes a discussion of the leading problems in systematic botany. The last chapters are devoted to history and geography, in which the distribution of plants and their evolution from the vegetation of early geological periods is discussed. All this is comprised within two hundred brief pages, and while the facts are clearly stated the book can hardly be considered as an effective introduction to botanical study. The proper introduction to botany is the study of plants, and while the facts which are here collected are very useful as references to persons who have some acquaintance with the science, this is not the kind of a work to put in the hands of beginners either as an aid or an encouragement to botanical study. The information given is such as persons of ordinary education might wish to possess, and persons who have some rudimentary knowledge of botany will find much enjoyment and profit in the book. It is not sufficiently complete for the specialist, on the one hand, though it may suggest to him at different points some interesting line for research, nor is it a book for beginners, at least not a book for young beginners. It belongs to a class of books, however, which is multiplying very rapidly in these days, when the work of popularizing science is considered so praiseworthy. If this phrase means the explanation in popular language so far as this is possible of the more important truths and principles which men of science have discovered, the object is certainly commendable. So far, however, as their leading purpose is to enable the student to obtain a knowledge of some science without personal study and investigation, they must always prove disappointing.

Notes.

Professor Halsted has sent out his check-list of American weeds, amounting to 751 species and varieties, without including those in sub-tropical Florida. There is a special list of one hundred of the worst or most annoying species.

The manual issued by the B. A. Elliott Co., of Pittsburgh, and entitled *A Few Flowers Worthy of General Culture*, is considerably more than a price-catalogue. It is beautifully printed, and some of the illustrations are unusually soft and delicate.

For hanging baskets the drooping Maiden Hair Ferns are not used as freely as they might be. Of these *Adiantum dolabrifolium* and *A. ciliatum* are especially adapted to basket culture by their habit. The second one will endure a much cooler temperature than the first, and is very distinct and elegant in appearance.

It is reported from Chicago that material for the horticultural display at the Columbian Exposition is beginning to arrive in large quantities from abroad. As an example it is stated that H. Cannell & Son, of Swanley, England, have sent one hundred varieties of herbaceous Pæonies and a large number of perennial Phloxes.

Mr. E. S. Nadal's interesting article on the "New Parks of New York," published in *Scribner's Magazine* for April, gains especial value from the accompanying map, as few persons even in New York realize how large are the areas set apart for public enjoyment, how diversely they lie, or what will be the extent of the proposed parkways connecting them.

In the last number of the *Gardeners' Magazine* Rev. G. H. Engleheart pronounces the White Trumpet Daffodil, Madame De Graaff, as perhaps the finest existing Daffodil. It is very large, of great substance, and is said to be a seedling from the Empress of India by the pollen of Albicans. It was introduced some three years since, but we believe the price is still a guinea a bulb.

During the past season twenty-four field meetings have been held by the Torrey Botanical Club, of this city, with an average attendance of twelve persons. One of the most interesting results of the year was the listing of all the plants on Sandy Hook, New Jersey, which was visited on July 25th. *Asplenium platyneuron*, a Fern which usually grows in rocky spots, was here found flourishing in pure sand, and among introduced plants *Lactuca Scariola* was noticed.

The Superintendent of Parks in Brooklyn says that Prospect Park "is visited by nearly thirteen million people annually, for its attractions alone, because it is little used as a thoroughfare between different portions of the city, as is the case with many other parks. During a storm the park is deserted by every one except the guards, but within half an hour after the skies clear the roads are covered by carriages, or, in winter, by sleighs, while snowflakes still linger in the air."

"No garden in Japan," says a recent writer, "is considered complete without its group of Maple-trees placed beside some artificial hill toward the west to receive additional splendor from the setting sun. Grassy slopes and valleys are planted with these trees, with the object of bringing into one limited prospect the red and golden tints in which the natural scenery of the wooded hills abounds. Picnicking and mushroom-gathering are pastimes which accompany the viewing of the Maple."

Arbor Day is now celebrated in Nova Scotia and New Brunswick, and in the *Educational Review*, published at St. John, an editorial on the observance of the day closes with some sensible suggestions like the following: Work should be the most important part of the programme; few trees should be planted, but they should be planted well and with careful preparation beforehand; school premises should be cleared up and beautified; the fatal mistake should be avoided of supposing that everything is done when Arbor Day is over.

In a bulletin just issued by the Experiment Station of the State Agricultural College at Michigan, Professor Taft, the horticulturist, reports on a test of different varieties of Strawberries last year that the most promising early sorts are Beder Wood, Lovett and Van Deman, while Haverland, Pearl, Parker Earl and Bubach No. 5 are the best which follow soon after. Of late sorts Belle, Florence and Gandy succeed the best. Of the newer Raspberries, Cromwell, a seedling from Connecticut, is in most respects similar to Souhegan, and thus far has proved more healthy and somewhat more productive. Of the late varieties, Royal Church, from Ohio, is one of the best.

Some tests made at the Kentucky Agricultural Experiment Station show that the Bordeaux mixture may be effective as an insecticide. Potatoes, which were infested and injured by the Flea-beetle (*Crepidodera pubescens*) were sprayed with the mixture, and the injury by insects was promptly checked. As new leaves unfolded between the sprayings the beetles would gather upon them, but were driven off as soon as the plants were sprayed again. The March blister-beetle, which appeared later in the field, avoided entirely the plants which had been sprayed, and although they occasionally gnawed the leaves of plants after the lime and copper had been washed off, it was plain the mixture could have saved the crop from most of the injury inflicted by these two beetles.

In an address read before the Wisconsin Horticultural Society, Professor Goff urges the young towns and villages of the west to set apart public pleasure-grounds before it is too late. He suggests that every village have its park, which shall be regarded from the beginning as an adjunct of the school, and be located sufficiently near the school-house to make it easy of access by the boys and girls. If the trees and shrubs are labeled with their common and botanical names the park will have a greater educational value, and if the planting is done with some ceremonies in which the young people can play a conspicuous part they will take more interest in it, and there will be less trouble experienced in securing from their parents

the money needed to maintain it, and this trouble will become smaller and smaller as the years roll on.

The *Journal of Horticulture* prints a list of varieties of Chrysanthemums, arranged according to the number of times each one was used at the exhibitions of the Royal National Chrysanthemum Society last year, and the average for seven years past. In comparing the first twenty-four on the list last year with the first twenty-four on the list in 1885 it is seen that very few changes have taken place—that is, all the favorite exhibition flowers of seven years ago remain favorites still. An examination of the relative positions occupied by the leading varieties during the last seven years shows no indication of decline in any of them. Among the incurved varieties the Empress of India has regained the first place, and among Japanese varieties Etoile de Lyon still holds the place it secured last year at head of the list.

The power of trees to regulate their own temperature to a certain extent is seen in the fact that their twigs are not frozen through in winter, nor does their temperature increase in summer in proportion to the temperature of the surrounding atmosphere. Their vitality protects them from both extremes. The bark is a bad conductor of heat, and is to a certain extent the clothing in which the plant is wrapped. Then the surface evaporation of the leaves produces in summer a freshness in them, and we know how cool they feel even on hot days. Evaporation, however, does not explain the coolness of many kinds of fruit that are enclosed in a hard envelope, through which evaporation seems almost impossible. The juice of a fruit grown by the Ganges is said by Hooker to be of a temperature of seventy-two degrees, Fahrenheit, while the sand in which it grew was found to be from ninety to one hundred and four degrees.

In the last number of *Insect Life* it is reported that the potato-tuber moth, which has been very destructive for many years in New Zealand, Australia and Algeria, has reached this country. Specimens received at Washington from Kern County, California, have been identified by Professor Riley. It was at first supposed that the insect had been accidentally imported on some of the steamers from New Zealand or Australia among the stewards' supplies. Later information, however, is that they were obtained from a Chinese gardener, so that it is not improbable that the insects were imported directly from China. The larvæ of this moth bore into the potatoes while they are still under the ground and after they are stored, and as much as three-fourths of the crop has been destroyed during a single season in Algeria. Strenuous efforts should be made to stamp out this pest before it obtains a foothold, and the immediate destruction of all infested potatoes is recommended.

Professor Kedzie sums up the results of experiments with Sugar Beets in Michigan last year, from the farmer's standpoint, that the outlook for the beet-sugar industry promises well over a large part of the southern half of the state. Some of the considerations which should incline farmers toward this industry is that the crop promises large cash-money returns, a good home market, and a concentrated product which costs little for transportation. Beet-raising properly conducted does not exhaust the soil, for the materials removed in sugar are only carbon and water, there being no nitrogen or potassium or phosphorus carried off, as there is in wheat. Besides this, the proper cultivation of Beets is the best preparation for a grain crop. In order to keep the soil from exhaustion the waste parts must be directly or indirectly returned to the fields. The tops and crown, not used in manufacturing, and the beet-pulp from which the sugar has been extracted are excellent cattle feed. In this way stock-feeding is a necessary part of the routine in a sugar-beet farm, and so is the rotation of crops. Beet-raising therefore compels thorough cultivation and good farming, which is a strong point in its favor. From the manufacturer's standpoint, it should be considered that a Beet-sugar plant is very costly, and that every device to reduce labor, save cost and turn out the largest and best product must be used when entering into competition with an established industry in the Old World. Americans now have a bounty of two cents on a pound, but they must contend with the experience and accumulated machinery of a half-century of beet-sugar-making in Europe. No such manufactory can succeed without an experienced and competent director, without abundance of good water, cheap fuel and transportation facilities, and unless it is located in a district with a suitable soil and climate which can be trusted to furnish 3,000 acres of Sugar Beets a year of good quality. In view of these facts manufacturers are cautioned to go slow.

The Sequoia Reservation.

LAST week we spoke of the efforts of a railway lobby to secure a right of way through Yellowstone Park. We might have added that every one of the forest-reservations which have been set apart for public use under the President's proclamation is threatened with invasion of one kind or another. When the Yosemite Valley was dedicated to public use there was a strong protest by men who hoped to use it for their personal profit. When it was found necessary to enlarge the reservation, so as to save the streams which flow into the valley by protecting the forests about their sources, the protest was still more energetic. Unless this area was included in the reservation, it was very plain that these highlands would soon be stripped of their timber, and this extension of Government control injured no one but unlawful trespassers. The land can never be subdued to agricultural use, and some of the mountains included in it rise above the timber-line. But the men who were selling timber which belonged to the Government, and the sheep-herders, who were setting forest-fires every year in the hope of benefiting the pasturage to which they had no right, were up in arms at once.

The big trees south of the famous Mariposa group have already been attacked, and one of the most important groves was taken possession of by a colony for the purpose of working them into timber. These wonders of the forest are a part of the nation's inheritance, and the trees are worth infinitely more as they stand than they would be when cut down and sawed up. If they are preserved they will draw visitors from all parts of the country and all parts of the world, and in a purely business point of view they would in the long run bring more money into the state as a natural attraction of unparalleled beauty and grandeur than they could in any other way. For the past year they have been protected by detachments of the army, which, under national authority, patrol the reservation. The

lawless men who covet the timber of these great trees have become enraged because the Government is undertaking to preserve the people's property. The California papers contain accounts of active efforts now being made there and in Congress to reduce the area of the reservation, and the sheep-herders are complaining that they have been deprived of their rights. A convention of the sheep men of three counties has lately been held for the avowed purpose of procuring the repeal of the act establishing the Sequoia Reservation, and it is well for the people and for Congress to know that if they relax their vigilance fires will again be sweeping through these forests and saw-mills will soon begin their desolating work.

No wrong has ever been done to a lumberman or shepherd by establishing these reservations. No man has a claim to pasturage on Government lands, still less right has any one to cut down the trees which belong to the people, or to kindle fires which will destroy not only the forest as it now exists, but all hope of forests in the future. The agitators for unlimited sheep-ranging boldly denied in convention all the truths in regard to the beneficent influence of forests which have been established by centuries of human experience. They asserted that the streams would continue to flow as evenly without forests as with them. They denied that the trampling and browsing of animals injure the growth of the woods. They even denied that fires are ever kindled in the interests of these sheep-herders, although every one who has ever been in California knows better. What they really want is full opportunity to steal the timber from the Government forests and to get rich by pasturing their flocks on Government land, where they are sure to do incalculable damage.

It is not probable that the Government will think of abandoning these forests, or any part of them, in obedience to a preamble and resolutions passed by a convention of would-be trespassers. But it is important that the people of the country should realize the need of constant watchfulness if these reservations are to be saved. Attacks upon them, open or insidious, may be expected at any time. The men who organize these attacks know just what they want and the most promising schemes for obtaining their ends. The individuals who take active interest in them, on the other hand, are few and scattered, and the reservations will never be permanently safe until their value is generally recognized throughout the country. No one will dare to attack them when an affectionate regard for them has become a universal public sentiment.

The Love of Nature.—I.

ALL human beings draw pleasure from nature in the rudimentary sense of enjoying fresh air, sunshine and a free open outlook. Every one prefers a bright day to a gloomy one, and a balmy air to harsh tormenting winds; and almost every one will confess that a green landscape is pleasanter to look upon than grimy streets, even though he may have good reasons for preferring a town as a place of residence. Such likings as these, however, prove no real love of nature. They are almost purely physical; they betray no more sentiment than the animal which is pleased when basking in the sunshine.

But the great majority of people, even among those whose minds are uncultivated and who do not practice the common proprieties of life, have a deeper feeling for nature than this, and can appreciate something of its true beauty. Stupid and brutalized indeed is the man or woman who does not notice a brilliant flower, or who would not be impressed by the view of a mighty mountain chain. On Sundays our parks are crowded with laboring people, who spread through every quiet walk and shadowy glade, and like nothing so well as to saunter or lie upon the grass; and although part of their pleasure is simply physical, any one who has sympathetically mingled with them knows that a great deal of it is of finer quality. The beauty of the

surrounding scenes impresses even the dullest eye and appeals through it to the most sluggish imagination. Even the roughest dweller in the tenement-house district admires the shores of the Hudson River when he sees them on some summer excursion, and is impressed by the beauty of the sea when for the first time he stands on a beach where giant waves are breaking.

This instinctive admiration for the beauties of the natural world is what many persons understand by the love of nature. But it is not, in the truest sense, the love of nature. It is distinctively a love for natural things which are beautiful, of course, but which are also unfamiliar and therefore striking. Let the dweller in tenement-houses inhabit a lodge in the Central Park for a while, and he might seek his Sunday entertainment in a down-town street. Let him work on a North River schooner, and he would quickly forget to notice the beauty of the shores. The same attitude toward nature can be observed in the case of persons of wider cultivation. Familiar natural features soon grow uninteresting. The artisans who crowd the park on Sunday enjoy its unfamiliar beauty more truly than most of the wealthier folk who drive there almost daily. It is curious, indeed, to see how few of these turn from the fashionable East Drive into the much more beautiful West Drive. And it is still more curious to find that hundreds of New Yorkers, who have made pilgrimages in search of natural beauty from the Nile to the Sierras and from the St. Lawrence to Mexico, have never left their carriages to see what the pathways in their own park might reveal. The Ramble is as unknown to them as if it lay in China, and they exclaim with surprise when you tell them that they might travel a thousand miles and see nothing prettier.

What people of this kind usually care about is not nature itself, but those conspicuous natural effects which are called scenery. Scenery is not the whole of natural beauty; it is only one manifestation of it; and a person who delights in a magnificent view, but finds all flat regions hopelessly tiresome, or who feels the grandeur of a rocky coast, but not the loveliness of a green-fringed quiet shore, does not really love nature. His attitude is like that of one who should profess to love flowers, but, while admiring a Rose, should despise a Forget-me-not. The true test of a love of nature is that one who gives interested attention to all natural effects and forms, and finds beauty where the average eye sees none.

Of course, there are grades and degrees of natural beauty, and for each grade the true lover will have the corresponding amount of admiration. He will not call a Belgian plain as beautiful as the valley of the Rhone, or declare that a Nettle has the charm of a branch of Apple-blossoms. But there are few plants which have no beauty of any sort; and there are few spots on earth where man's hand has not obliterated Nature's intentions entirely, so wholly devoid of charm that the sensitive eye and mind cannot enjoy them keenly.

Admiration, says a French writer upon art, "is the active æsthetic form of curiosity." And this means that he who really admires the works of God will be lovingly curious about the Hyssop on the wall as well as about the Cedar of Lebanon; will see more to please him in a rough bit of pasture-land than the average person sees in a whole fertile valley. Who can love nature better than the landscape-painter who spends his whole life in transferring its beauty to canvas for the instruction and pleasure of his fellow-men? But no one is less in need than the landscape-painter of what is called scenery. It is not he who greatly prefers the cañon of the Yellowstone to the banks of the little river near his home. When he is brought to face magnificent scenery he experiences keen delight, but he gladly comes back to his quiet plains, his placid pools, his little forest-glades. Nor is it merely because these things are better fitted than grander things for transferring to his canvas. His own small corner of the world is enough for him, as a thing to enjoy no less than as a thing to paint. Delacroix was not a landscape-painter, and so cannot be

suspected of looking at inanimate nature with an eye for good subjects; and there has never been a painter whom we could more easily credit with an inborn love for striking and even spectacular kinds of beauty. But fine scenery was not essential to his enjoyment of nature. "The poorest little alley," he wrote one day from a shabby suburb of Paris, "with its straight little leafless saplings, in a dull and flat horizon, can say as much to the imagination as the most bepraised of sites. This tiny cotyledon piercing the earth, this Violet shedding its first whiff of perfume, are enchanting. I love such things as much as the Pines of Italy."

This is the voice of the true lover of nature, and like it was Corot's voice, which constantly praised not the grandeurs which he had seen on his travels, but the tender, subtle beauties around his home at Ville d'Avray, and, more than anything else, the humblest of them all, "my leaves and my little birds." If one is born to love nature, or learns to love nature, as these great men did, and as all true artists do, the quietest scenes are impressive—the most familiar are ever new. A Blackberry-vine trailing over a gray rock gives one an emotion as delightful as the sight of a giant mountain; and custom cannot stale one's pleasure, for it is as infinitely varied, as perpetually renewed, as the leaves on the trees, the blades of grass in the field, the tints in the sunset sky.

Notes of a Summer Journey in Europe.—XIII.

THE Botanic Garden at Brussels is probably most famous and best known through the work and writings of its present Director, Professor F. Crépin, the distinguished rhodologist, who has made the species of Roses a special study for thirty years. It is very nearly a hundred years since the first botanic garden was established in this city, and it was for a time an adjunct to the School of Medicine. The site of the garden of to-day was acquired in 1826 by a private association having the name of the "Royal Society of Horticulture of the Low Countries," which was changed eleven years later to its present title of the Royal Society of Horticulture of Belgium.

The garden passed through several periods of success, misfortune and embarrassment until 1870, when it became the property of the Government, and it is from this time that it has taken high rank as a scientific institution. Previously, being private property, it was of comparatively little use to the public, and the work carried on was chiefly horticulture pure and simple. The total area of the garden is only about sixteen acres, but, although it is not so large as some others, it takes rank among the best-kept and best-equipped public gardens in Europe. But it is not given so much to the formation of a collection of rarities or novelties as it is to furnishing a fair representative and instructive botanical collection within its small area. The aim has been to get typical examples of the different genera and to introduce the most remarkable species, preference being given to those which are native.

In addition to the open-air collections, those of the green-houses contain a larger and more varied assortment than might be expected, and in very good order. These, added to the botanical museum and valuable herbarium, afford excellent opportunities for study by students of the university and others. The *Victoria regia* house contains some very fine specimens of the great Amazon Lily and also a good representation of other aquatic plants.

The larger portion of this botanic garden is as freely open to the public as is compatible with good order, and it is as freely used as a park by the populace. A small portion is given up to the "School of Botany," or a collection of plants, arranged according to the classification of Dumortier, which is available to all regular students and those really interested in the study of plants from the botanical standpoint. Plants of a tender or alpine nature are often protected from the hot rays of the sun by small wicker hood-like screens about two feet in height.

A portion set apart as a "School of Floriculture" is designed to furnish practical information about live plants to gardeners, florists or any who may be at all interested in a garden, and it is freely open to the public. Into this collection the most notable of the new introductions are annually introduced, so that the amateur may see and appreciate the merits or demerits of a novelty before purchasing it for himself. Some of the beds make a handsome show, and the condition of the plants goes

far to prove that botanical science and instruction and good cultivation may all be accomplished together. Too often botanical collections are mere aggregations of species and give little idea of the capabilities of the individuals under favorable conditions or good cultivation. There are enclosures devoted to collections of officinal and poisonous plants and to those of economic value as food or in manufactures, all such being grouped together which have the same peculiar value.

The small area of the garden precludes the possibility of establishing an arboretum or systematic collection of trees and shrubs, but a considerable number of species have been massed together on the western side. Conifers, apparently, do not thrive. A system of instructive labeling has been introduced here, which has been copied at Copenhagen and perhaps other places. The labels are made of heavy sheet iron, those of an average size being cut a little over six inches wide and nearly nine inches long. They are painted, and the family, botanical name (and chief synonym, if any), common name and habitat are given; and on the same label, immediately underneath the foregoing information, a map of the world is neatly painted, which shows the geographical distribution of the species. These labels are very neat, and are said to endure exposure for many years without material injury or effacement. They cost from about thirty to sixty-five cents each, according to the size and amount of work required, and they may be procured by application to officers of the garden. This form of label would be rather too costly for most botanical establishments, and for all practical purposes the name of the native country of the plant should be sufficient.

The species of Roses in the garden have a particular interest because they are the special study of the distinguished Director. I noticed among them the true *Rosa foliolosa* of the south-western states, although here growing less vigorously than at the Arnold Arboretum. This little Rose is extremely rare in cultivation, and the plants under this name sometimes belong to some other common species. The occasional flowering throughout the summer of *Rosa rugosa* is here considered as simply an accidental, and not a reliable, character. But *R. Indica* is a true remontant, and a hybrid of this and *R. rugosa* is found to be quite hardy here. The flowers are white, fairly double, fragrant like *R. rugosa*, and the blossoms are produced continuously. The foliage and habit are somewhat like those of *R. rugosa*.

The principal large park in the city is mainly shaded by fine Beeches and English Elms, but Horse-chestnuts, Maples and Lindens also enter into the composition. It is surrounded by a double row of the broad-leaved Linden (*Tilia platyphyllos*), planted uniformly apart, with their trunks free from branches for twelve feet, and with the tops squarely clipped off at eighteen feet from the ground. The branches of the trees in the rows are interlaced, while the sides are cut hedge-fashion. In short, the whole thing might be called a hedge raised twelve feet in the air, and it is an example of a once popular kind of tree-pruning still often met with in many French towns.

In the Place du Petit Sablon I noticed another relic of a fashion which years ago came into vogue in some parts of Europe, and a hint of which is shown when flower-beds are ornamented with shells, light-colored stones, and the like. A number of small formal beds are arranged with lines of dwarf Box, *Sempervivum* or Feverfew, the intervening masses being filled with evenly broken small sandstone of two kinds, one being of a grayish color, and the other reddish. These are thickly put on the ground alternately with each other, or with the plants. At a little distance the result is quite deceptive, and equally effective as would be the use of the more expensive *Sempervivum*. The broken sandstone is also used as borders to formal beds. The practice will commend itself to those managers of public gardens, squares and cemeteries who are economically minded, but have a mania for formal designs, such as geometrical figures, monograms or names.

Arnold Arboretum.

J. G. Jack.

Flowers in Town.

IT is hardly possible now to draw that distinction between hot-house flowers and garden flowers which was formerly so clearly marked. Not many years ago few plants were grown under glass in winter which could be grown outdoors in spring, summer or autumn. Greenhouses were kept chiefly for exotics, and women were content to adorn themselves, while snow lay upon the ground, with such flowers only as nature had originally given to their sisters of other lands. When Roses were out of season, they wore Camellias; and while waiting for the spring to make the bulbs blossom in their flower-beds, they filled their conservatories with importations

from the Cape. Now, however, it would be impossible to feel sure, from the flowers in our drawing-rooms and our florists' windows, what the season of the year might be. While utilizing the resources of other climes more fully than ever before, we have also transplanted our own summer gardens indoors; and every year an interested observer may notice new favorites from the border, and even from the roadside or the woodland glade, contentedly blooming in the florist's shop in winter and in especial variety as Easter approaches.

Persons who are not yet middle-aged can remember their surprise at seeing for the first time Lilacs and Lilies-of-the-valley before the snow was off the ground; yet now even the street-venders offer them to us. Until I was grown up, I never knew what a Daffodil was, because I always lived in New York in the winter and spring, seeing the country only when Daffodil-days were well over. "Early spring flowers" meant to me, in my childhood, nothing earlier than buttercups and daisies. But the city child is more familiar with the sight of Daffodils than most of her country cousins. Violets are easier to get in midwinter than in spring, and Roses are common all the year round.

This year, long before Easter-day, our streets were gay and redolent with spring and summer flowers, some of which it was very hard to believe had been raised in greenhouses with a definite idea of pecuniary gain. We have got accustomed to associating the traditionally modest Violet, beloved of the spring poet, with winter festivities, and it now seems as much a flower of the ball-room as of the woodland. But the still more modest Forget-me-not is yet instinct with sentiment, connecting it with brooks that wander through open fields and nestle into pools beneath the shadow of young-leaved Willows. Were these Forget-me-nots, which lay on the street-vender's bench while winter lingered in the air, really grown near at hand in artificial warmth, or had they been brought on the wings of a gracious wind from some softer southern clime? And the Lilacs themselves, were they really not yet in bloom on Long Island? Were not these outdoor-looking sprays of white and purple broken off recklessly by bare-foot boys standing on the fence, but carefully cut by a gardener's shears in a carefully heated house?

Still more surprising was it to see true denizens of the wild-wood blooming in pots as placidly as though they were Camellias. It was, indeed, a proof that our own country had come to town as well as that eastern lands had come west and tropic lands had come north, to be able to choose, for an Easter gift, between gorgeous Orchids, Bermuda Lilies, veritable Azalea-trees and blossoming shrubs of Mountain Laurel.

I have heard people say that it is a pity things have changed in this fashion. They feel that it is best, for the sake of securing that variety in our pleasures which means a perpetual freshness of interest, to limit ourselves in winter to the thousand exotics which we can get by artificial cultivation only, and to leave our own spring to bring us its own treasures in their turn. And they feel that this is best, also, for the sake of preserving that sentiment with regard to flowers which plays so great a part in the delight they give. They would have us render unto spring the gratitude that is spring's, and not forestall and cheapen it by thanks bestowed upon the clever gardener. They would have us recognize the procession of the seasons by not disturbing the natural procession of the flowers, and mark our months, as the Japanese do, by the special enjoyment of the special offerings of each.

But people who feel thus, I think, are usually those who live all the year round in the country, and when they come to town to see what we are about can afford to pity our confused, un-sentimental way of mixing up Nature's bounties, sure themselves of receiving these bounties, gradually but continuously, in their true and most beautiful sequence. Or else they are persons who at least can leave town when they choose and watch not merely the Daffodils unfolding but the fuzzy gray buds swelling on the Willow-bushes.

To others who, like myself when I never saw Daffodils, spend only two or three summer months out of town, a confusing of Nature's sequence of gifts cannot matter so much. To them who never see the grass growing green except in a park, and who in a park cannot tell which early flowers have been transplanted from the hills just across the river, and which have been brought from across the sea, such flowers do not wear the associations that they wear for country-bred eyes. It matters not to them whether they first see Lilacs or Hyacinths, for they do not know which would bloom first out-of-doors. What they are chiefly concerned with is to see them both as soon as possible, and as many of them both as they can. It may be shocking, from the rural point of view, to as-

sociate Daffodils rather with a dinner-table in February than with a garden-border in April, and Lilies-of-the-valley with winter weddings rather than with dewy mornings in early summer. But how can they help it? And, deprived as they are of the better part, why should not they fill their lives as full of beauty as they can, even though Nature's processes be artificially forced, and Nature's order of things almost reversed? They cannot grow their flowers, or even watch nature grow them; and if they must buy them, ignoring whence they come, it cannot matter much whether they come from under glass or from under the greenwood-tree.

However, whether it is "right" or "wrong" to anticipate the seasons as we city folk now do with the help of the florist and his greenhouse, no one will question that it is right to bring the country to town in another fashion which has likewise developed vastly in very recent years. Surely it is an unmixed pleasure to think that no city child need now ignore the fact when the first spring wild flowers really begin to blossom a little way out of town, or when New Jersey gardens are at their best. Scarcely any wild flowers or common garden flowers came to us, even in their proper season, a few years ago. Now all the familiar kinds come, and not flowers alone, but the first hints and promises of flowers, and autumn witnesses that flowers have been. Pussy Willows come first, and budding sprays of shrubs that will bloom out in water, and then Marsh Marigolds and Trailing Arbutus and Jack-in-the-pulpits and Apple-blossoms, and so on to the outdoor Lilacs and Daffodils, cheapened now within reach of the slimmest purse, and the Mountain Laurel, not now in little pot-grown shrubs, but in big and splendid branches, and Swamp Honeysuckles and Daisies and Buttercups and bunches of Clover; and so on and on until summer is over and the wild flowers and common garden flowers are gone, and the bunches of Black Alder-berries come, and the streets are full of Chrysanthemums, and the reign of forced and coddled, coaxed and transposed greenhouse productions begins again. Truly, if our florists' windows now defy and contradict the calendar of the seasons, there are many months when our streets illustrate this calendar faithfully for any eye that knows how to interpret the pictures which Flora draws.

Foreign Correspondence.

London Letter.

UVA GRASS.—The following inquiry comes from a Californian correspondent: "Will you kindly inform me of the name and habitat of a gigantic grass of which I forward a few sprays? It is not grown here, but is imported and sold in a dry state under the name of Uva plumes. The plume itself is monstrous, being four or five feet long. The sprays droop entirely on one side, reminding one of the fleece of a Cashmere or Angora goat. The people who furnish the plumes in Europe will not give the name of the grass." I received a similar inquiry from an English correspondent nearly four years ago, and found that the plumes were then offered for sale by London florists under the name of Uva Grass. How they were obtained is not quite clear, some stating that they came from the Congo, others from India. On comparing the plume at the Kew herbarium it was found to be the male inflorescence of *Gynerium saccharoides*, a gigantic reed which grows on the river-banks of Cumana in Venezuela, and in Brazil. It is one of the most beautiful of all tropical grasses, the stems being twelve feet long, an inch in diameter, with leaves five feet long and one inch in width, the edges serrate and channeled along the midrib. In habit the plant is not unlike *Arundo Donax*. The panicle is terminal, at least four feet long, copiously branched and plume-like, the branches a foot and a half long and clothed with small flowers, which, when dried, are gray-brown in color. The plumes sold in the English shops are six feet long, including the stalk; they are extremely elegant and feathery, but are sometimes disfigured by dyes of various colors. There is a large plant of this grass in cultivation at Kew. It is grown in the tank which in summer contains the *Victoria regia*, and is as striking in appearance as some of the Bamboos. No flowers have as yet been produced by this plant. It is probable that the plumes sold in London, and also, apparently, those now sold in America, are imported from Brazil.

Some of the plumes were among the exhibits from the island of Dominica at the Colonial and Indian Exhibition held in London in 1885. It is by no means unlikely that this *Gynerium* could be grown in the southern states, particularly Florida. I have never seen or heard of any other plant in cultivation in Europe except that at Kew, which was imported direct from Venezuela about fifteen years ago.

SARRACENIAS AS FLOWERING PLANTS.—It is probable that you know a great deal more of the decorative value of *Sarracenia* than we do here. They are not by any means popular with us, being generally classed among botanical curiosities. But a well-grown and properly colored specimen of *S. Drummondii* or *S. flava*, or even of *S. purpurea*, is, in my opinion, an object of very considerable beauty apart altogether from its peculiarities of structure. We have numerous hybrids and seedlings of *Sarracenia* now, and at Kew there is a good representative collection of both species and varieties. They are grown in pans in a well-aired sunny greenhouse, except for about a month in early spring, when, after repotting, they are placed in a stove temperature and exposed to all the sunlight possible. Of course, they are kept very moist always. Under this warm treatment the new leaves, which are developed in March and April, grow rapidly, and lay the foundation for brilliancy of color in autumn. With the new leaves the flowers are pushed up. Hitherto we have removed most of the flower-buds to further the growth of the pitchers, but this year we left them to expand. They have been quite sensational, many of the flowers being five inches across. In form they vary somewhat, and in color they range from cream-white to bright yellow and rich crimson. These flowers are as pleasing as the most elegant Daffodils; they are fragrant, and last a week, at least, in water, and their colors are good. *Sarracenia* certainly deserve to take rank among first-rate flowering-plants for the greenhouse. I have never seen a *Sarracenia* grown out-of-doors in England that was satisfactory, nor have I seen imported wild plants with pitchers as fine as they produce under cultivation.

THE WEATHER here for the last week or so has been as exceptionally warm and sunny for April as it was previously cold and dull. The consequence of the change is apparent among the early-flowering trees and shrubs in the open air. Almonds, the most beautiful of all spring-flowering trees, and a common street-tree in the London suburbs, besides early Cherries and Plums, are already laden with flowers. *Forsythia suspensa* is a cloud of lovely yellow bloom, beautiful almost beyond comparison as a bush, and even more attractive when trained against a sunny wall; *Acer rubrum*, with its clusters of bright crimson flowers, *A. hybridum*, with its yellow clusters, and several others are now attractive. *Parrotia Persica* is even better than the Red Maple, several plants of it at Kew being now thickly laden with clusters of rich red flowers. It is a beautiful tree in leaf, and in autumn it assumes the richest colors before the leaves finally fall. The early Rhododendrons, such as *R. Dahuricum* and *R. Nobleanum*, are bright with flowers in the open borders. The rich mauve-purple of *Daphne Mezereum* is seen to advantage when the plants are grown in large groups, two round beds of it twelve feet across, and each containing about twenty-five plants two feet high, and nearly as much through, being especially effective. The small alpine *D. Blagayana* is also in flower on the rockery. *Pyrus Japonica*, in its several varieties, is in full bloom, the most attractive, on account of its rich blood-crimson color, being that called *Moerleesii*. The Daffodils on the lawn are again a "waving sea" of yellow. The Crocuses, now over, have been equally showy. They are from the bulbs which had been used for forcing, and instead of being thrown away they were planted in grassy slopes on the lawns.

FLOWERS IN APRIL.—The supply of these for the English, and especially the London, market comes from Italy, France, Belgium, and our own small islands in the south,

as well as from the English gardens proper. It is interesting to find quantities of the feathery *Mimosa* (*Acacia dealbata*), *Richardias*, *Anemones*, *Lilac* and *Wallflowers*, all, or nearly all, from foreign sources. Orchids are gaining ground yearly as market flowers, considerable variety being now obtainable at the stalls. Good *Cattleya*-blooms can be purchased for sixpence, and *Odontoglossum crispum* for threepence each. *Dendrobiums* of several kinds are generally abundant, *D. nobile*, perhaps the best of all species, being very largely grown for the English flower-market. *Liliums*, *Daffodils*, *Tuberoses*, *Eucharis*, *Freesias* and *Gardenias* are generally abundant, and consequently cheap. Of course, *Azaleas*, *Camellias*, *Roses*, *Carnations*, *Hyacinths* and *Tulips* are sent in enormous quantities almost every day.

INTERNATIONAL EXHIBITION OF FRUIT.—This exhibition will be held on a piece of ground adjoining the Thames Embankment, and will be opened on September 28th next. Valuable prizes will be offered, and efforts are being made to obtain special features among the exhibits, such as collections of fruit-trees, showing the different methods of training, pruning, etc., also collections of fruiting trees grown in pots. It is probable also that lectures and demonstrations will be given, with the view of teaching the uninitiated something of the art of producing high-class fruit in England. London will be exceptionally rich in great horticultural exhibitions this year. Besides the usual important displays at Regent's Park, the Crystal Palace, the Temple and Chiswick, we shall have the above great collection of fruit and the International Horticultural Exhibition, which will open at Earl's Court on May 7th, and will continue throughout the summer. I have already informed you of the general plan of this exhibition, which promises to be a success, the greater portion of the vast space available for horticultural exhibits being already taken. Most of the principal London nurserymen have promised their support. Grottoes with banks of Palms and Ferns, Egyptian, Greek, Italian and other gardens, fountains, variously colored electric lights, high-class music, beside many other attractions, are being rapidly prepared. Altogether the exhibition promises to be both novel and interesting to the professional man as well as to the ordinary visitor. The *Gardeners' Chronicle* states that "the exhibition must be looked upon solely as a commercial venture, in which the District Railway and other parties are specially interested." Most exhibitions nowadays are commercial ventures, more or less. The play's the thing, after all.

London.

W. Watson.

Plant Notes.

Some Recent Portraits.

THE colored plate published in *The Garden* on the 5th of March is devoted to a portrait of *Cerithe retorta*, a member of a genus pretty generally distributed over Europe, northern Africa and Asia, and containing some showy and useful border plants. *Cerithe retorta* is probably the most beautiful member of the genus, and is a native of the Peloponnesus and of Dalmatia. It is a hardy annual, growing from one to two feet high, with much-branched stems. The lower leaves are obovate and stalked, while the upper leaves clasp the stem by two rounded auricles. The flowers, which protrude above the showy purple floral bracts, are yellow, tipped with purple. This is a plant which might be expected to flourish in the United States, where the hot dry summers should help its development.

In the issue of the same journal for March 19th there is a colored plate of *Streptocarpus Galpini*, a species recently discovered in the Transvaal, near Barberton, by Mr. E. E. Galpin, who sent seeds of it to Kew in 1890, where it flowered in October of last year. The discoverer describes it as growing in crevices in the cliffs and under rocks, and only on the tops of the mountains just below the highest summits. *Streptocarpus Galpini* is closely related to *S.*

Dunni, and, like that species, has but one leaf and a many-flowered raceme, although it differs from all other species in the form of the corolla, with a short and broad tube and a spreading almost regular limb. The color is rich blue, tinged with purple, the throat being pure white. The flowers are produced in slow succession, and continue to expand in cultivation during about five weeks. Mr. Watson, who has been so successful in hybridizing plants of this genus, was naturally anxious to cross *Streptocarpus Galpini* with other species and varieties, but his first attempt failed to produce good seeds.

In the March 19th issue of the *Gardeners' Chronicle* *Trichodesma physaloides*, a handsome boraginaceous plant of southern Africa, is figured. It is a herbaceous perennial with a fleshy root-stalk, from which are produced annually many erect stems which form clumps two feet across. The leaves are glaucous green, and the corollas, which are an inch across, are pure white. Mr. Adlam, of Pretoria, in the Transvaal, who has secured a stock of this plant, contributes to the columns of our contemporary the information that "*Trichodesma physaloides* grows near Pretoria on dry bare hill-sides at an elevation from 5,000 to 5,500 feet, and that it is an herb one to one and a half feet high with tuberous roots, the leafy stems dying down in our dry winters, appearing again with the first summer rains." The flowers are produced through the early summer, and it is a profuse bloomer. The flower-stalks and sepals are dull purple and the corollas are white. "It is suggested that the treatment given to tuberous *Begonias* would suit the wants of *Trichodesma*."

New or Little-known Plants.

Miltonopsis Bleui splendens.

THIS new Orchid is a garden hybrid raised in France by Monsieur Bleu, and it is the most distinct and beautiful among many hybrids of great promise which he has produced. It has attracted great interest, apart from its beauty, from the fact that it is the first hybrid *Miltonia* ever produced. It is the result of crossing *Miltonia vexillaria* with *M. Roezli*, plants which a few years ago were found rather difficult to cultivate, and were generally known as *Odontoglossums* of the *Miltonia*-flowered type, in which class were included *Odontoglossum Phalæopsis*, *O. Roezli*, *O. vexillarium* and *O. Warszewiczii*, all of which are now recognized as *Miltonias*.

It was only in the spring of 1872, after failures by Hollis and Roezl, that Chesterton succeeded in delivering live plants of *Miltonia vexillaria* to Messrs. Veitch & Sons, one of which, and the first one to flower in cultivation, flowered in February, 1873, in Veitch's establishment. Roezl succeeded in 1873 in delivering one solitary plant of *Miltonia Roezli* to Mr. Bull, of Chelsea, England, for a large price, and this flowered in December the same year, and created as much sensation as *M. vexillaria* had the previous spring. Thousands have, however, been imported since that time of both varieties, and have become so popular and well known that no description of them is necessary.

The plant of *Miltonopsis* raised by Monsieur Bleu was secured by Mr. Sander, of St. Albans, who called it "a marvel," and from him Mr. Ames acquired a part of the plant.

It is intermediate in character and habit between the parents, and I think will prove of good constitution. The plant now carries two flower-spikes of three flowers each well above the foliage. The flowers measure in length four and a quarter inches, and the lip three and a quarter inches across. The sepals and petals are full, as in *M. vexillaria*; the base of the petals is suffused with delicate rosy purple on white ground; the lip is large and flat, bilobed in front, and of a delicate white color, faintly veined with pink; the base of the lip light chocolate, with twelve to fifteen radiating lines about an inch in length, of a

deeper color, while the three lines on the crest are of a reddish brown. We have grown this plant at the warm end of our *Odontoglossum*-house, near the glass, and close to where we grow plants of *Miltonia vexillaria*, and it receives the same treatment as regards potting material, temperature, etc., which is given to *Miltonia vexillaria*. The plants should never be allowed to get dry, and yet care should be taken not to give them too much water while they are resting. The temperature should be kept at about sixty degrees night and day, or fifty-five degrees in extreme cold weather, with free ventilation. They should be moist continually, and the plants kept well up to the light, but not in direct sunshine.

North Easton, Mass.

W. Robinson.

Garden Market in the months of April and May are for the most part produced at Ham, where only the finest types are planted. Under the special methods of cultivation adopted these flowers attain a much greater size and finish than in ordinary gardens. Of course, there are numbers of enthusiastic private growers. Mr. Peter Barr is now searching the Pyrenees for new types, and such amateurs as the Rev. G. H. Engleheart are making interesting experiments in hybridizing. But at Ham, on the rich level ground of Mr. Walker, the Daffodil is grown purely for the market, and therefore perfection in the individual flowers is aimed at rather than the acquirement of a varied collection. Here the bulbs are now approaching full bloom. The spring is late this year in England, and thousands of flowers, representing all the leading sections, but a few varieties only in each section, are dancing in the wind.

Cultural Department.

An English Daffodil Farm.

THE Daffodil is to England what the Hyacinth is to Holland, and during recent years the golden chalice flowers have become more in request for all forms of floral decoration. We hear much of the great bulb-farms of the Low Countries, but quite as instructive and more pleasing as a picture is a Daffodil farm, where upon true market scale the principal flower of an English spring is grown as it is by Mr. Walker, whose broad acres adjoin the picturesque common of Ham, almost under Richmond Hill, in Surrey, about ten miles from London. The flowers that surprise and delight the visitor to the Covent

In 1884 the great Daffodil Conference gave an impetus to the cultivation of this flower, which amounted to a fashionable craze, but the effect of competition was to reduce the price fifty per cent., and while in 1884 it was computed that ten million bulbs were grown in England, the number is now over two hundred millions. In 1890 the flowers were sold at the rate of twelve bunches for ninepence, this reduction being due to the large and early consignments of good flowers from the Scilly Islands, Channel Islands and the south of France.

It is only when the produce is inferior that Daffodil-growing ceases to pay. Mr. Walker believes in the best cultivation, and therefore he always secures good prices. The soil is deeply dug, and before planting it is plowed, harrowed and rolled, to afford every encouragement to a vigorous healthy growth.

Naturally, the same conditions will not suit every variety alike. Some, as the so-called Whites—that is, the light-colored forms, as *Cernuus*—requiring a warmer position than those of more robust constitution, as the bicolor *Empress*. It is very interesting to note how differently Daffodils behave under the same conditions, and in 1881 Mr. Walker planted a trial bed of the various forms to test their behavior, the soil being strong loam of good depth. The result was that such varieties as *Capax* and *Cernuus* soon disappeared, but the more robust forms, like *Horsfield's* and *Empress*, thrived with surprising vigor. Manure is used only for the *Trumpet* and other robust Daffodils.

As far as possible the bulbs are lifted annually, although it seems a formidable task to go over beds two hundred to three hundred yards long. Mr. Walker places great faith in this an-

and it will be useful to indicate them as they are possessed of strong constitution and bear the finest flowers. It is necessary to weed out well for such a purpose, where the list of Daffodils includes some eight hundred forms, many of them, however, differing in a slight degree, and chiefly in color, ranging through all shades of yellow, from a pure lemon tint to almost clear white, and pure white in those *Narcissi* of which the *Pheasant's-eye* is the leading type. Among the *Trumpet* varieties the greatest faith is placed in *Empress*, although popular opinion seems to incline more toward the noble bicolor raised by John *Horsfield*, the Lancashire weaver. To an uneducated eye little difference can be seen between them, but the *Empress* increases more freely, blooms more profusely, and the flowers are of better substance than those of *Horsfield's*, which by reason of their softness do not last so long in full

Fig. 31.—*Miltonopsis Bleui splendens*, in the collection of Mr. F. L. Ames. The flowers, natural size.—See page 197.

nual lifting, and would serve all alike if it were possible, but a compromise is made by lifting the common kinds every two years and the best varieties each year. To this treatment is due the superb vigor of leaf and flower noticeable in all his plants. The bulbs are lifted when the leaves have died down, and they are dried, cleaned and replanted in the following August or September, the first variety to be planted being *Ornatus*, one of the *Poet's Narcissi*. They are planted in long beds, about five rows in a bed, and the soil is raised a few inches above the bed to keep the bulbs from stagnant water, as the growth suffers in places where the beds slope down to the ordinary level.

—Although a thoroughly representative collection of Daffodils is grown, those kinds cultivated largely are few in number,

beauty. But both are splendid varieties, the trumpet beautifully shaped, bold, rich yellow, and in striking contrast to the creamy white and robust perianth. The flowers of both attain surprising dimensions and show remarkable clearness of color, and it is not unusual to find here six and seven flowers proceeding from one bulb. When visiting Ham last year I found in a row of *Empress* one bulb carrying no fewer than eleven blooms, each of fair proportions. When we come to the true yellows a post of honor is given to *Emperor*, a superb Daffodil, splendid in form, color and size, a rich mass of yellow, and used much in the English parks, where it is planted in distinct beds to give the full richness of the handsome flowers. *Maximus* is another favorite, with flowers of the deepest yellow, splendid in shape, but, unfortunately, the

bulbs do not always display vigor in constitution. Golden Spur, one of the earliest to bloom; Countess of Annesley, Edward Leeds, Princeps, and the lovely little Tenby Daffodil, *N. obvallaris*, may also be named. Of the *Incomparabilis* section the varieties chiefly grown are *Cynosure*, *Gloria Mundi*, *Lady Watkin*, and *Sir Watkin*, the boldest of the four. Of the *Barri* group, *Maurice Vilmorin*, *Conspicuus* and *Mr. Ingram* are more largely grown than any others, while of the beautiful *Leedsii* forms those selected comprise *Gem*, *Duchess of Westminster*, a beautiful flower, chaste, sweetly scented and admirable for cutting, *Minnie Hume* and *Madge Matthews*. It is necessary to say little respecting the white trumpet Daffodils, as they seem to find little favor, although the varieties display tones of lemon and cream as subtle and pretty as in the choicest exotic. Those that have a good place are *Mrs. Thompson*, which increases more quickly than the others, *Pulcher*, *Cernuus* and *Mrs. F. W. Burbridge*. The *Burbridgei* forms are also more for the Daffodil fancier than the grower for market. The flowers are the essence of grace, and most delightful in their delicate shades, but require more than ordinary care to preserve them in true character. Of the *Poeticus* group *Ornatus* holds first place, the flowers always, by reason of their earliness and sweetness, commanding a good sale, and many would name this as the most popular *Narcissus* grown in England. *N. Poetarum* and *N. recurvus* form a succession, the list closing with the lovely *Gardenia*-flowered double *N. poeticus*, fl. pl. Mr. Walker has tried to force this variety, but without success. Other varieties grown largely consist of *Odorus*, *Odorus Nigilobus*, the double flowers like *Codlings and Cream*, and the old *Orange Phoenix*.

In the season scores of busy workers can be seen in the large packing-house getting the blooms ready for the market, bunching them together in twelves. The Daffodil seems an ideal market-flower, as it bends at right angles to the stem, thus facilitating bunching or conveyance in boxes to distant places. There are few things that travel so well, keeping fresh for even several days when carefully packed. It is important to gather the flowers before they fully expand. At Ham they are gathered when about half-open, and in the case of *Ornatus* still earlier, but they open in fresh and perfect condition.

Kew.

Hardy Ferns.

A BED of Ferns will certainly afford the real lover of plants as much satisfaction as he can derive from an equal area devoted to any other use. The hardiest species will grow in almost any partly shaded place, but even these do much better where their needs are carefully attended to. A border along the north wall of the dwelling is usually a suitable location. The bed should be deeply dug, and the soil, even when sandy, mixed with half-decayed leaves for something more than mere porosity. Last year I witnessed an illustration of the benefits of thoroughly overturning the soil. One end of my fernery is filled with the beautiful *Ostrich Fern* (*Struthiopteris Germanica*). The group of plants, each with its vase-shaped funnel of leaves, was the especial admiration of visitors, and I never wearied of watching the plume-like fronds unfold in spring, each pinna down-curling at the tip like the veins of the feather from which the Fern takes its name. But two years ago a drain had to be laid right under these plants at no small hardship to the Fern-roots. It would have been no wonder had they all died after such rough usage, yet they made a fair show that summer; and last year, so rich and rampant was the growth that we felt we had gained a new conception of the capabilities of a much-prized plant.

In addition to the kind mentioned above, I would recommend the little *Bladder Fern* (*Cystopteris fragilis*), which makes a low growth under the *Ostrich Ferns* and is useful for bouquets; the *Christmas Fern*; the finer forms of *Aspidium spinulosum*; *Clayton's Fern*, with its hint of variegation and its odd habit of fructification, and, above all, our common *Maiden Hair*, which the author of that somewhat rare English book, *My Garden*, calls "one of the most lovely of all Ferns." There are many other useful species, though one needs to be careful or the border might be filled with plants whose fronds perish early, like those of the *Cinnamon Fern*, and leave a vacancy behind.

An edging of cobble-stones makes a suitable line of separation between a Fern-bed and grass. A similar row can be placed at the right distance from the wall to catch the pelting fall from the eaves if water-spouts are lacking, and will also prove a welcome protection to the roots of some delicate plants. Of course, the bed can be beautified by introducing a few other modest plants, whose flowers will help by contrast

to heighten the soft effect of the green fronds, and, therefore, between the Ferns and over the gray stones of the border, *Violets* can grow and any other wildling one especially likes. *Trillium grandiflorum* is very handsome through May. A recent addition to my collection, *Collinsia verna*, was charming last spring. The wild *Ginger* (*Asarum Canadense*), though brought home in the first place for further study of its curious flowers, would not be spared now on account of the decorative value of its leaves.

As my own fernery serves more as a botanical Snug Harbor, where plants can be kept under surveillance, than as a pleasure-garden, not all its inhabitants would be of general interest. Yet, even with that drawback, it is rarely without some special attraction apart from the constant beauty of the Ferns, from the first twinkling of the snowy stars of *Blood-root* to the last heads of *Eupatorium*. I have not, as yet, had success with *Cypripediums* or any *Orchid*, but the pleasures of the place depend little on doubtful ventures. Most hardy shade-loving or woodland plants will thrive, some of them in unexampled luxuriance, when removed here from the hard competition of wild life. And no part of one's demesne is likely to yield greater satisfaction than the plot wherein grow roots of one's own collecting.

Geneva, O.

S. F. Goodrich.

Shading Greenhouses.

IT will not be many days before the annual question of greenhouse-shading must be considered in all houses where summer flowers are grown. In fact, shading to some extent is required at most times when seedlings are coming on and propagation of any kind is attempted. The annual whitewash always seems to me a crude operation and a makeshift, one of the followings of precedents which is so much easier than the striking off into new paths. New paths do not always bring one safely through, but if the old one has known difficulties it is better to venture the new sometimes on chance of gain. It has become a habit to cover the glass of greenhouses as soon as the sun becomes powerful with a film of lime-wash, white-lead in benzine, or some similar coating, to remain through sunny and dull weather until shortening days allow its removal. In large ranges this is, no doubt, the quickest, cheapest and handiest way to protect the contents of a house from scorching, but it is not an ideal one. When the air is clear and the sun is shining with power the translucent glass will admit light enough to keep the plants in fair health, but most plants would be more vigorous if a certain amount of sunlight could reach them. No substitute has yet been found for sunlight which will keep man or plant in good heart. But if the plants suffer somewhat in bright weather, they deteriorate rapidly in long spells of wet, gloomy weather, especially when a little cool and evaporation is slow, for at such times rust quickly gathers and mildew often appears.

Perhaps in large establishments no improvement could be made on the present economical procedure, but it does not follow that the amateur with a small house should content himself with imitating the operations of his commercial neighbors. Aside from the imperfections noted above, applying a wash to the glass of a house is a distinctly unpleasant operation, only equaled by the temper-wearing labor of thoroughly removing the same at a later period. Cotton cloth has seemed to me worth a trial. By tacking the cloth to frames of the right size the greenhouse can be covered quickly and effectively, and it makes a good shading, though not very durable. Cotton cloth is not dear, and even at the additional expense this method seems an improvement on the wash.

Looking around for some suitable material for shading I found at a Japanese goods store some *Bamboo-screens*, made of narrow strips of *Bamboo*, woven together with thread or cord. These are very cheap, and should be fairly durable. The screens are to be had in different sizes, those of three by six feet being most useful for me. In using them I run copper wires from the ridge to the lower wall three inches from the glass, and work the screens by the simple expedient of drawing them up with a cord and allowing them to drop out of the way by gravity. A neater arrangement would be to fasten them on spring rollers, which would probably need to be well oiled at first to prevent rusting. The wires would be required with these also to keep the shade at the right distance from the glass. Now, when I wish shade in any part of the house, it is a simple matter to slip in a roll and pull it up to its place, and it is as quickly dropped out of the way. Where hanging plants are grown, it will be necessary to hang them from the girders. If the vines are properly tied out from the glass the screens will work well above them. This is not an

ideal arrangement, but it is an improvement on the former one for my purposes. Its advantages are that it is cleanly and handy. It is quickly applied, and as quickly removed. In dull weather it is out of the way, and the plants have the benefit of all available light. When it is up, and the sun is shining ever so strongly, some of its rays filter through to keep the moisture in motion, which is an important point, and to keep the plants in good heart. The screens being three inches from the glass there is this air-space filled with hotter air rising to the ventilators and helping to keep the lower air cooler. At least it seems to me that on a hot day, with the sun shining, it is distinctly cooler under these cool-looking shades than it was when the wash was used. This may be partly imagination, but as I am not sure that my plants do not possess some of that useful faculty, perhaps they may be affected by the same influence. With the flickering sunlight over them, my plants can scarcely fail to keep in good condition, especially as the shades are dropped at night and the early morning sun is allowed to flood the house.

Elizabeth, N. J.

J. N. Gerard.

Tomatoes from Immature Seed.

IN the Eighth Annual Report of the Wisconsin Experiment Station Professor Goff reports a series of tests which have been conducted for several years to show to what extent plants may be modified by the selection of seeds. In the fall of 1883 seed was taken from mature fruits of Cook's Favorite Tomato and from other fruits of the same variety which had nearly attained their full size, but had not commenced to change their color. The next year plants were grown from both these selections of seeds, and in the autumn seed was taken as before from ripe fruits of the plants grown from ripe fruits, and from immature fruits of those grown from immature fruits. This was continued for four years, and again in 1889 the experiment was repeated with seed which had been saved from fruit grown in 1886, so that there has been secured one strain of Tomato grown through six generations of seeds known to be fully mature and another strain of the same number of generations from immature seed, and the two strains have been grown side by side.

The effect of this selection upon the plants is made very clear by illustrations in the bulletin, which show that the plants from immature seed have been perceptibly reduced in size, while their prolificacy has been increased. Ten plants grown from ripe seed last year, after the fruit had been picked, weighed more than twice as much as the same number of plants from immature seed. Ten plants from ripe seed up to the middle of September had matured 1,298 fruits, while the plants from unripe seed had matured 2,519 fruits which weighed nearly twice as much. Besides these differences the use of immature seeds has plainly tended to promote early maturity, and in a comparison carried on for five years the strain from unripe seed gave fruit on an average twelve and a half days earlier than the other strain. The size of the fruit from immature seed has been reduced about one-twelfth. This fruit is less firm than that from ripe seed; the rind is thinner; it has a somewhat greater tendency to ripen unevenly, and it is often slightly green at the centre when appearing ripe externally. In keeping quality it is inferior to that from ripe seed, as a rule. In form it is more oblate, contains more cells, and has a greater tendency to grow double. The posture of the plant has been rendered more decumbent, while the color of the foliage has been uniformly lighter, and its tendency to blight has been noticeably greater.

In summing up, Professor Goff thinks that the following practical lessons may be deduced from these and some other experiments with feeble plants:

"1. The results suggest that in our climate the Tomato, at least its more rampant-growing varieties, may be rendered more productive and earlier in maturing by a treatment that reduces the native vigor of the plant. Growing the plants on rather poor and dry soil, pinching the growing points, or root-pruning should accomplish this end.

"2. The health of plants is in a degree dependent upon the quality of the seed used. In these days of severe competition in the seed trade, dealers are doubtless often tempted to use immature or otherwise unsuitable stock for seed. The popular demand for cheap seeds tends to deteriorate quality in this commodity, and consequently in our crops, and to render the latter more subject to disease.

"It must not be understood that the use of immature Tomato-seed is sanctioned or recommended in this article. The experiment is not as yet complete, and it is too early to announce its full teachings."

Early Spring Flowers.

AT the last meeting of the Pennsylvania Horticultural Society Mr. John Bell read a paper on the "Garden in Spring," from which we extract the following paragraphs relating to the earliest flowers:

If the ground is not covered with snow in February one of the most striking features one would see in taking a walk through our grounds would be beautiful carpet-like masses of the yellow Buttercup-like flowers of the Winter Aconite (*Eranthis hyemalis*) and groups of the different varieties of the Snowdrop. These grow in the shade of a large-leaved Magnolia-tree (*M. macrophylla*) on a slope facing east, where the grass will not grow in summer. A few steps farther, on the margin of a group of the Great Laurel (*Rhododendron Maximum*), we come on a group of Christmas Roses (*Helleborus*) in varieties from pure white to dark purple, some with green flowers and some with greenish white flowers. Beyond these are Crocuses in many colors, with their flowers opened while the sun shines on them, and in the near distance can be seen the male blossoms of the Filbert or Hazel-nut, and the catkins of the Goat Willow, which are very beautiful at this early season.

The various evergreens, both trees and shrubs, are very cheering at this time, some of the oldest trees having their trunks covered with varieties of the evergreen English Ivy. Among the broad-leaved kinds near the house are groups of hybrid Rhododendrons and Azaleas, *Euonymus Japonica* and its varieties, *Daphne Mezereum*, *D. Laureola*, *D. Pontica*, *Kalmia latifolia*, *Leucothœ Catesbæi*, *Heather (Erica carnea)*, *Ilex glabra* and *I. verticillata*, with its red berries hanging on all winter, and all helping to lighten up the dreary season in February and March.

At the close of March and in the early days of April appear on the margins of these groups of shrubs the various species of Primula—*P. Japonica*, *P. Sieboldi*, *P. vulgaris* (English Primroses), *P. veris* (Cowslip), *P. elatior* and other hybrids, Spring Snowflake (*Leucojum vernalis*) and Summer Snowflake (*L. æstivum*), Wood Anemone and *Anemone Pennsylvanica*, Moss Pink (*Phlox subulata*) and its varieties, with the Spreading Phlox (*P. divaricata*), and the various kinds of Scillas.

Then we have in sheltered places a beautiful variety of evergreen herbaceous plants starting into new growth, after lasting all the winter green and fresh. Among these are *Arum Italicum*, the Madonna Lily (*Lilium candidum*), *Pachysandra procumbens*, the Christmas Fern (*Aspidium acrostichoides*), four species of Yucca (*Y. filamentosa*, *Y. Gloriosa*, *Y. glaucescens*, *Y. angustifolia*), Butcher's-broom (*Ruscus aculeatus*), *Hypericum calycinum* and Evergreen Candytuft (*Iberis corraefolia*). A very large tree of the white Yulan Magnolia (*M. conspicua*) stands surrounded with a thick growth of the Children's Bluebell or Grape Hyacinth of English meadows (*Muscari racemosum*), intermixed with the Tenby Daffodil (*N. obtusiflorus*), one of the first of the family to bloom, while on the shady side of the tree a group of the wild English Cowslip (*P. veris*) is in bloom at the same time. Then follow in succession the many species and varieties of the Narcissus family, the good old Daffadowndilly, Butter and Eggs, Pheasant's-eye and the rest, coming into flower one after another until May, and with the last of these are associated the white and purple flowered Wood Lilies (*Trillium grandiflorum* and *T. erectum*), the Wild Tulip of the English woods (*T. sylvestris*), the blue alpine Anemone (*A. alpina*), the double and single flowered Pile-wort (*Ficaria ranunculoides*), our beautiful native Dicentras, the Blood-root and the various sorts of Dog-toothed Violets. Of course, this does not include all the interesting hardy flowers among the earliest ones, for there are Fritillarias and Violets, the Siberian Columbine and Twin-leaf, and many more, but surely here is a list which ought to be able to brighten any rock-garden or border from the time that snow falls until the trees are in leaf and before the gay season of Peonies and Roses.

The Forest.

Timber-culture in Eastern Nebraska.

A VISIT to a region where land has been secured under the timber-culture acts will convince any one that the sciences of those "proving up" claims were often quite elastic, and the forlorn appearance of many of the trees and bits of woods proves that the legislation failed to effect the beneficent end it proposed. But some of the claims give evidence of hopeful possibilities in timber-culture. Last winter I was at the farm of Mr. James Stephen, a business man of Central

City, Nebraska, 130 miles west of Omaha, or very near the ninety-eighth meridian and not too near the arid region for trees to do fairly well. The farm is on the south side of the Platte, which here comes near the bluffs, and lies on the margin of the plain, which rises considerably higher than the river-valley. The plain is carved along its edge into irregular masses of knolls, which form the bluffs. These are separated by numerous little valleys called "draws," which come down from the plain to the river-valley below, and through them the water flows from the edge of the plain above when it falls in sufficient quantity. There is scarcely any trace of a stream-bed, for there are no pebbles or stones to mark it, and the little hollows are soon overspread with grass and other plants. The draws are an evidence of a climate dry at some seasons, but with rain enough at times to run down the slopes and wash out the earth.

It was on the slope of one of the draws that the principal plantation stood, near where it started from the plain, so that it had essentially the same prairie-like soil. This is a dark clay or marly loam, mixed with some sand. The quantity of sand in the soil of the bluffs increases, and the soil becomes less productive as the river-valley is approached. The aspect of this tract of trees was eastward, with a slight bearing to the north. Smaller areas had been planted on the tops of the ridges nearly on a level with the plains and more exposed to the wind, for it was evident that the slope protected the trees to a certain extent, since they were smaller on the west side, where most exposed to the prevailing winds. When the claim was approved by the Government there were 6,800 trees on five acres of ground. This amount is far from excessive when compared with what may be borne on an acre, but they stood quite close together and would soon need thinning, though a natural process of thinning would soon begin. The species chiefly planted were Black Walnut, Elm, Box Elder, Ash, Catalpa, Red or Silver Maple, Sycamore and Honey Locust—the first three kinds predominating. The Cottonwood was discarded as undesirable, though a few had obtained a foothold. The owner took the most pride in the larger tract of three and a half acres, where the trees had been planted six years and most of them were from two to four inches in diameter and from eight to fifteen feet high. The majority of the vigorous trees on the larger area would average three inches in diameter and ten to twelve feet high. As yet all species had grown to about the same height, although there was a difference in the character of the tops, which varied somewhat in accordance with the natural habits of the trees. The bark showed a healthy growth, being close, even and free from fungi, insects or anything injurious. The few Cottonwoods accidentally present served for comparison, having made a larger growth in the same time, the boles being from six to eight inches in diameter and the trees from twenty to twenty-five feet high.

The Black Walnuts were of special interest on account of their greater economic importance than most of the other kinds. Most of them were fine straight specimens, and in sufficient quantities in many parts of the grove to occupy the ground exclusively when they needed the space for development. How high they may grow or what dimension of trunk they will attain can only be determined by the future, but at six years of age they were very promising. As the Black Walnut is indigenous to eastern Nebraska, this is also in its favor. It is found north of Central City in the vicinity of the Elkhorn River and north-west near the boundary of South Dakota, on the bluffs of the Niobrara and its tributaries. Professor Bessey has found it as far west as the one-hundredth meridian. In central Kansas, Indian Territory and in Texas it reaches ninety-eight and a half degrees west. Trees on the Niobrara were two to three feet in diameter, and lumber had been manufactured from them. The altitude of Central City is about 1,800 feet; that of the region about the Niobrara (Long Pine Creek) 2,250 feet. Fruit was observed clinging to the branches of the Box Elder (a common tree also along the streams where any timber was seen), Sycamore, Ash, Honey Locust, Catalpa, and I was told that some of the Black Walnuts had borne.

These groves had been carefully attended, and the weeds kept down till the trees were large enough to care for themselves or did not allow the ready passage of a horse and cultivator between the rows. The main implement used besides the hoe was a triangular harrow, like the old-time corn-cultivator, with drag-teeth extending two or three inches below the beams, not far enough to interfere with the roots of the young trees. The tops now form a canopy sufficiently dense to shade the ground and prevent the growth of grass and injurious weeds, and the leaves are already lodging about their roots and beginning to form a mold, so that forest-conditions of soil have

already begun, and such wood-plants will only grow as flourish in the shade. The trees had also been judiciously pruned. Owing to climatic conditions there would probably be greater need of this in Nebraska than in the forest-region farther east, for in the western edge of the forest-belt, and where it stretches out along the rivers, there is observed a special tendency of the trees to branch low down. One of the first characteristics noticed by a person familiar with the appearance of forests along the Mississippi and eastward, and passing through this region for the first time, is the low habit and widely spreading tops of the trees seen along the streams. Many of them are nearly as broad as high, with very short trunks and bushy crowns. The general facies is that of trees growing in an orchard. Several trunks may at times be seen starting from the surface of the ground, or but little above it, as if the trees were huge overgrown shrubs, or had developed from stool-shoots springing up from the base of a tree of earlier growth which had passed away. This was always very pleasing to the eye, for nearly every tree with such a habit was ornamental, but it would not be as useful for timber. From this tendency of the climate trees that are planted would doubtless share in this habit, and extra pruning, or very close planting, would be necessary to counteract it. An orchard of Plum and Cherry trees on the farm showed the same habit in an impressive way. From trunks barely more than a foot high limbs freely branched, giving all the trees the appearance of dwarfs, much like an orchard of dwarf Pear-trees. They had compact, well-rounded tops and were very shapely, and even handsome.

There was another view of timber-culture suggested by these groves, the bluffs and draws along the Platte. Much of the land is poor, especially near their margin, with soil too thin for profitable cultivation and becoming dry in summer. Then the land is rough with countless little valleys and knobs, often with steep sides like those bordering a ravine. It would seem advantageous for the greater part of such a region to be given up to forest-culture. If furnished with trees they would in time supply a large amount of useful timber to a contiguous region greatly in need of it. The valley is broad, from three to ten and twenty miles, and essentially flat, but with a downward slope sufficient to give the river a strong current. The river itself is usually a mile or more in width, but very shallow. The water in many parts of it almost, or quite, disappears in the summer season, making its way as a subterranean stream in the loose earth, which is reached by digging a few feet beneath the surface of the ground. Though it has doubtless shifted its bed more or less from side to side in the valley in the past and cut away the bluffs and widened its flats, it is evident that the valley owes much of its width to the slow disintegration of the plain bordered by the bluffs, the water from the edge of the plain passing down through the draws and cutting them slowly back, for the elevations bordering the draws, or scattered through them in their wider parts, are of all shapes and sizes, from little knolls but a few feet high to small hills with tops on a level with the plain, and everywhere shows the erosive action of water. A forest covering land circumstanced like these bluffs would prevent additional wear and transportation of the richer soil from the edge of the plain into the valley below.

The trees growing here corroborate what a study of the best rain-charts indicates, which is, that fully half of Nebraska, aside from the region of sand-hills where they come into its eastern part, is so situated with regard to precipitation as to make the growth of timber practicable, while belts along the streams extend the region still farther west. Then it is to be borne in mind that the dry season, or time of least precipitation, is the winter, the period of rest for trees, so that they receive their supply of moisture in the growing season when most in need of it.

Transplanting the Trailing Arbutus.

To the Editor of GARDEN AND FOREST:

Sir,—Admirers of the Trailing Arbutus, or May-flower (*Epigæa repens*), may be glad to know that this charming plant can be successfully transplanted to one's home grounds with reasonable certainty of success. At least such is my experience after having transplanted several, which at this writing (April 20th) are in full bloom for the second time since they were placed beneath the Laurels, Huckleberry-bushes and scrub Pines skirting my lawn. The first plants set out were taken up February 2d, 1891, having been brought from an open hill-side about a quarter of a mile distant. On the following

day three unusually large, long-stemmed plants were received by express from a locality over twenty miles distant, the earth being mostly loosened from the roots by the shaking the box had received during transit. The last-mentioned plants had a precarious existence for a time, and considerable portions of each died; but the surviving portions became in due time floriferous and made new growth. The others did not for a moment seem affected by the change, but grew vigorously and bloomed most profusely. The last of October a friend brought me a plant which he had taken up carefully and placed in a basket; this grew uninterruptedly after planting, and is now in bloom. In December one of the plants set out in February had to be again transplanted, on account of the removal of the tree which shaded it. It apparently received no injury from this second transplanting, and is now as full of blossoms as the other plants, although it was one of those whose survival after the first transplanting I for some time despaired of.

The dates of transplanting were various, and in no instance according to rules "laid down in the books." The secret of my success consists, I think, in three things I was careful to observe, as follows: (1) Remove the plant without disturbing the roots, though experiment No. 2 shows that plants which have their roots nearly denuded may be saved by careful replanting. (2) Select a place for replanting which has conditions of soil, exposure, etc., as nearly as possible like those where the plant originally grew. (3) Plant carefully.

The best way is to cut all round a plant with a spade, not less than two inches beyond the extremities of the longest stems; the entire piece should then be carefully lifted by running the spade horizontally underneath, at least three (better four) inches below the surface of the ground; the whole should then be placed in a basket on damp moss, and replanted at once. In replanting remove a piece of surface-soil a little larger and deeper than the piece to be planted, the difference in depth to be made up by the addition of sand, or sand and fine gravel; then carefully insert the piece, firming it down well, especially about the edges, and fill in whatever space there may be around it with sandy or gravelly soil firmly impacted.

While the plants set out soon after being taken up grew most vigorously, it is among these that the most unpromising specimens are now found. The present bad condition of these I attribute to the disturbance of their roots by pulling out grass which had begun to crowd and choke them. The plants which had been nearly dried by shaking off the soil from their roots during transportation were planted on a dry hill-side, under low-branched scrub Pines, and consequently have not had the grass to contend with, which, doubtless, accounts for their continued improvement since convalescing.

Easter Flowers in Philadelphia.

To the Editor of GARDEN AND FOREST:

Sir,—The season just past showed an increased demand for flowering plants in the celebration of this festival, and though a greatly increased supply was provided the local market was not overstocked. The Lilies continue to hold first place among Easter flowers, and generally they were of very good quality, the stocks being about equally divided between *L. Harrisii* and *L. longiflorum*, though there is some reaction of opinion in favor of the latter for Easter use, while *L. Harrisii* will probably retain its precedence as an early-forcing variety. Some of the commercial growers produced fine specimen Lilies by planting four or five bulbs in an eight or ten inch pot, and many of those grown in this manner produced from thirty to forty flowers, and for certain purposes such groups are admirable. Plants of this character are too costly, however, for general retail purposes, and a majority of flower buyers prefer a single-stemmed Lily when well-grown and crowned with five to ten large flowers. *Lilium candidum* is but little grown now for Easter use, though a charming plant for cut-flower arrangements. Some few other species have been tried to a greater or less extent in the past few years, among them *L. auratum* and some varieties of *L. lancifolium*, but though they are beautiful in themselves, yet they do not attract much attention from the buyers of Easter flowers, and consequently these ventures have not proved profitable.

Cytisus and Hydrangeas were also plentiful and met with a ready sale, small and medium-sized Hydrangeas apparently being most in demand, and since the season was late there was no difficulty in getting these plants in flower at the proper time without resorting to hard forcing. Azaleas continue to hold their place among the indispensables for Easter decoration, and they were not overplentiful this season, at least those

of good quality. Comparatively little change in varieties was seen among the Azaleas, most of them being such standard sorts as Madame Vander Cruyssen, Eugene Mazel, the white Bernard Andreas, Borsig and a few others, the most notable among the newer varieties being *Vervæniana* and a bright crimson named Flambeau. The latter has a very striking color, and will doubtless soon become better known.

Bulbous stuff, in general, was not of remarkably good quality, though some fine Tulips and Von Sion Daffodils could be seen, the Daffodils being very popular for corsage-bouquets at this time. In cut flowers the quality was good, Roses in particular having been favored by the cool days immediately preceding Easter; this made them more firm in texture, and consequently more lasting. Among Orchids the flowers of Cattleyas, *Cypripedium Lawrenceanum*, *Dendrobium densiflorum* and a few other *Dendrobiums* were chiefly used. Some cut blooms of *Anemone Japonica* could be seen, and, though pretty, they attracted but little attention.

As usual, a great many Palms were used, few decorations seeming complete without more or less of these most graceful of foliage plants. Araucarias, too, were used to some extent, and though very durable for house-decoration they are somewhat expensive, from the fact that so far they have nearly all been imported from Europe. This is likely to be remedied in a few years by the propagation of sufficient stock on this side of the water, for European importations are frequently disappointing from the number of imperfect plants they contain.

Holmesburg, Pa.

W. H. Taplin.

Spraying Machines and Insecticides.

To the Editor of GARDEN AND FOREST:

Sir,—Will you name some portable spraying apparatus suitable for the needs of a small place—a garden with fruit-trees—and their approximate cost?

2. Is there any way to circumvent the aphid on the Snowball, which attacks the under side of the leaf so that it curls up?

Whitewater, Wis.

Albert Salisbury.

[So many manufacturers make good pumps for spraying with insecticides that it is hard to say which is the best. For work like that mentioned by Mr. Salisbury a Knapsack sprayer would be satisfactory. One called the Eureka is made by N. Bokel & Co., of Philadelphia, which has a good apparatus for spraying the under side of leaves; this costs \$21.00. The Galloway sprayer, which is about one-third cheaper, is made by Albinson & Frusheim, of Washington. The Excelsior sprayer, which costs about as much, is made by Stahl, of Quincy, Illinois. The Field Force Pump Company, of Lockport, New York, have a sprayer of a different pattern and at nearly the same price, and a still cheaper one is named the Ideal, and is made at Egg Harbor, New Jersey. If Mr. Salisbury would apply to the experiment station in his state, no doubt Professor Goff would tell him which machine he finds most effective there, and our readers generally will receive intelligent answers to questions relating to insecticides and fungicides by applying to the horticulturists at the experiment stations of their various states.—Ed.]

The India-rubber Tree.

To the Editor of GARDEN AND FOREST:

Sir,—The bushy habit of specimens of *Ficus elastica*, mentioned in a late issue of GARDEN AND FOREST, may be secured by forcing, with the best conditions of soil, temperature, etc., but many amateur growers do not have these conditions. To check the upward growth of a large plant which was making rapid headway in our garden two years ago, a band was tightly wrapped below the topmost leaf. The growth in this direction was checked, and several branches soon started out along the main stem. When these were well grown the band was removed, so as to allow asymmetrical development. This method is better than that of cutting off the main stem.

Insects on Cherry-trees.

To the Editor of GARDEN AND FOREST:

Sir,—I have several Cherry-trees which seem to be fairly vigorous, but each year they are covered with black insects

which destroy the fruit and render the foliage unsightly. Can you suggest an efficient remedy?

Brooklyn, N. Y.

T. G.

[These insects are the ordinary and often-destructive Cherry-lice (*Myzus Cerasi*). They appear early in the season without attracting much attention, but they multiply very rapidly if the weather is warm and dry. The remedy for them is to spray the tree with the kerosene emulsion diluted fifteen times, or with whale-oil soap-suds, in the proportion of one pound of soap to eight gallons of water. Two ounces of crude carbolic acid added to the mixture will make it more effective.—Ed.]

Notes.

From a Carnation-house one hundred and twenty-five feet long and twenty feet wide near Philadelphia, chiefly planted with the variety Lizzie McGowan, there were cut during the season up to the 1st of April more than 70,000 flowers.

The reports from different cities in the country, which were published in the *American Florist* last week, show that the trade in flowers for Easter was larger than it has been for years. The stock of Lilies was unusually large, but not a flower seems to have been wasted.

Among the shrubs of comparatively recent introduction is a Japanese member of the Witch Hazel family called *Corylopsis pauciflora*. It has short drooping racemes of yellow flowers, which appear before the leaves, and it is really an admirable garden-plant, which ought to be better known.

A peculiarly fine effect in mahogany (says a writer in *The Sun*) is obtained by sawing crotches. A piece is sawed just above and just below a point where two limbs shoot out on opposite sides. When such a piece is properly cut up into veneer, the crotches show in beautiful plume-like markings through the middle of each sheet.

A recent writer, describing the winter aspect of the geyser-basins in the Yellowstone Park, says that one of the most interesting features of the hot pools is the continued growth of vegetation throughout the year. In certain spots underground heat preserves an even temperature in the earth, no matter how cold the atmosphere may be; and, in consequence, rich patches of green may be found entirely surrounded by masses of ice and snow.

Mr. George Klehm has for some years been growing Tulip-bulbs at his place on the shores of Lake Michigan, near Chicago, and every year he is successfully and profitably enlarging his business. In a paper read before the Florists' Club of that city it was argued that Mr. Klehm's experience had demonstrated that the business of raising Tulips, and perhaps some other kinds of Dutch bulbs, could be made a profitable industry even in the climate of Chicago.

In reply to several correspondents who wish to write to their representatives in Congress concerning the attack on Yellowstone Park we would say that the vicious scheme to grant exclusive privileges to the Montana Mineral Railway Company is House bill Number 4545. It has already been reported favorably in the house. Senator Warren's bill, which reduces by one-half the forest-reservation adjoining the park, has also been reported back from the committee to the Senate. Its number is 2373.

A correspondent of the *Gardeners' Chronicle* complains that throughout the Forest of Dean and elsewhere where there are large woods, swarms of men, whom he calls "Fern-tramps," are constantly gathering Ferns, which they carry away in large sacks for sale. In many places rare varieties of Ferns are almost exterminated. To this the editor adds that he has seen bushels of Ferns exposed for sale on costermongers' barrows in the streets at eightpence per dozen, at which rate there soon will be very few left in the country.

Winter Sweet is the appropriate English name given to *Toxicophlæa spectabilis*, one of the interesting woody plants which have been more or less crowded aside to make room for the more popular Orchids. A portrait of this plant is given in the last number of the *Gardeners' Magazine*, which has come to hand, and well shows the flowers crowded into axillary corymbs and wreathing the long branches with white blossoms. The fragrance of these flowers is very sweet and penetrating, and the plant does not need the stove treatment

which is usually given to it, for it thrives perfectly in a temperate house, although it does not flower so early. Plants of this kind will not suffer neglect, and they too often are little less than eye-sores, but if they are carefully cultivated, specimens in full health are beautiful objects, and will remain so, from year to year, for a long time.

The public reservations of all kinds in the city of Washington, including the parks proper and the small spaces which are called squares, circles and triangles, but excluding the Botanical Garden and the grounds of the Department of Agriculture and the Soldiers' Home, amount to about 400 acres. Two hundred and sixty-eight acres are estimated to be in a condition which needs no further improvement, eighty-three acres to be partly improved, and forty-six as yet wholly neglected. The Botanical Garden covers ten acres and the Agricultural Grounds cover forty acres.

The Parapee Palm (*Guilielma speciosa*) is cultivated by the Indian aborigines of the Guianas for its fruit, which they largely use as food. They plant it about their settlements, and where it is found apparently wild in the forest, examinations will show that such situations were formerly occupied by the Indians. In some seasons the fruit is produced without seed—that is, it consists entirely of pulp, like the plantain and banana, while in other seasons it contains seeds; this variation occurs in the fruit of the same trees from season to season, and plants raised from these seeds show the same characteristics of variation in the fruit. When boiled or roasted the fruit has something of the texture and taste of a very dry mealy potato. It is palatable, very nutritious, and residents in the interior have a particular liking for it. When ripe the exterior covering of the fruit is yellow, thin, and only slightly fibrous, while it is mealy and yellow within. The fruits, which are individually about the size of a pigeon's-egg, are borne in bunches of from forty to sixty together. There are two or three bearing seasons in a year.

We have spoken on more than one occasion of a disease which attacks the Sugar Beet, and which has been identified with the scab fungus of the Potato discovered by Dr. Thaxter; and now, according to a bulletin just issued by the Indiana Experiment Station, a new disease of this Beet has been discovered in the form of a bacterial parasite which does not cause the death of the plant nor show any spots on the surface nor any discoloration of the tissues. A puffed condition of the mature leaves, and their smaller and paler development, are its best external signs, and it is shown in the root when cut open by the greater prominence of the fibre, a yellowish tint and a less firm texture. The microscope shows the presence of numbers of bacteria in all the tissues, although the gross characters already given do not enable one always to separate healthy and diseased Beets. It is not known yet how the disease is transmitted from plant to plant, and no method of averting it is suggested. Its insidious character is plain from the fact that it has so far escaped detection or even suspicion, although examination showed that it was common throughout Indiana, at least. The disease is certainly a matter of serious importance to all who cultivate or use the beet crop because it decreases the sugar contents of the beets materially. In some cases studied at the station the loss amounted to as much as fifty per cent.

The horticulturists and fruit-growers of the United States have demonstrated their alertness to grasp new ideas in the speedy adoption of the practice of spraying to protect their orchards and vineyards against insects and fungi. The practice on the other side of the Atlantic in this direction is much less advanced than it is here. Almost all of our experiment stations have issued instructive little manuals on the subject, which any one can have for the asking, and these manuals answer almost all the questions which any intelligent fruit-grower will ask. Bulletin 86, which has been just issued by the Experiment Station of New Jersey, contains in twenty pages almost all the information needed by those persons who intend to use insecticides and fungicides during the coming season. It does not pretend to give any new information, but in a concise way it gives all the necessary directions as to the selection of machinery, the preparation of insecticides and fungicides, the method and time of application, etc. There is no need of repeating any of this advice here, since it has all been given more than once in these columns, but it is worth while to remember that a spraying-machine of some kind has become a necessary part of the machinery on every farm, and no gardener, fruit-grower or farmer should rest satisfied until he has prepared himself with the proper apparatus and has learned how to use it intelligently.

Formal Gardening.

THE little book entitled *The Formal Garden in England*, which was reviewed a few weeks ago in this journal, is very interesting in its descriptions of some old English places, and it is not seriously injured because in the warmth of their enthusiasm the young authors are moved to commend some samples of alleged garden-art which would be ridiculous if they were not dignified and almost hallowed by historical associations. It is plain that the authors have no clear idea of what the masters of that art mean when they speak of the "natural style of gardening," and yet the book appears to exist not so much to commend the formal gardens of Old England as to condemn another kind of gardening, to which the authors refer under the name of landscape-gardening. We call attention to this, however, not to take sides in any controversy, but simply to repeat what has often been said in this journal, that there is no reason why one kind of gardening only should be used; indeed, there is every reason why different styles should be employed for different purposes in different places. More than this, the fact that one has an intelligent appreciation of true landscape-art does not argue any inability to enjoy the best examples of formal gardening. Indeed, it is probable that one with the catholic sympathies and free imagination which enable him to take pleasure in beautiful gardens of every kind has a more genuine and consistent delight in formal gardens than the professed champions of this style exclusively.

The first essential of a formal garden is, of course, its formality, or perhaps we should say its mathematical symmetry both in surface and outline. In connection with this we are accustomed to see conspicuous brightness of color, but the very best examples of formal garden art may exist without brilliant colors, and, indeed, formal flower-beds where carpet patterns are reproduced in emphatic colors are so often used in places where rigidity of outline and vividness of color are conspicuously out of place that they

have done very much to prejudice persons against the very name of formal gardening. It has been said that the garden is an essential part of the dwelling, and that therefore it must have the same kind of balance, regularity and finish, or, in other words, that the immediate surroundings of the house must have architectural treatment, and the methods which have governed the design of the house should be carried out to the surrounding grounds. It is not true that this is the only way to make a consistent house-scene that is to bring the house into perfect harmony with the grounds, but it is one way, and a very good one in many cases, to produce a homogeneous result. In more spacious areas, like public parks, there are places where, in connection with terraces, promenades and similar constructions, the planning and the planting can have this same formal and architectural character with the very best effect.

It must be remembered, however, that quite as much skill of one kind is demanded to make this formal treatment effective as there is of another kind of taste and training to produce a good landscape-picture. It is true that many efforts to create or improve scenery in this country and in Europe are dismal failures; it is equally true that examples of the best formal planting are even more rare than those of the most effective natural planting. When it is decided that formal treatment is the best for any particular place we are at once brought to face the real problem in the situation. Creative faculty is needed here as truly as it is in any of the other arts of design, and where shall we look for the artist who has been trained for such work? Very plainly the men who are skilled at laying ribbon-lines and constructing portraits of eminent citizens out of Echeverias are not to be trusted. Ornamentation of this latter kind is too crude to be classed as art. And yet the student will find little that is better than puerilities of this sort. We stand in need of both precept and example, and it is to be hoped that the next work on formal gardens will attempt to lay down some of the canons which should control their design and construction.

For success in the best architectural gardening no man can have a sense of color too refined or too clear an idea of the beauty of form and proportion, and yet it should be remembered that, at its best, garden-art of this kind appeals to the sense of beauty alone, and while it may give the keenest pleasure we should remember that there is a higher art which addresses itself to the nobler part of man's nature. A natural landscape or a genuine work of landscape-art possesses something more than beauty, something beyond perfection of form and color. Its essential charm is in the inner meaning to which it gives expression so as to move the feelings and touch the heart.

The Love of Nature.—II.

ONE frequently hears persons who are planning for their summer in the country declare that this year they want to "go somewhere else and see something new," not because they have any special fault to find with their former place of residence, but because they are tired of the especial phase of natural beauty which it offers them. The mountains one year and the sea the next, or at least a change from one mountain or sea-side place to another, is the rule of summer life with many people. They would be surprised to be told that it is the rule because they care little for nature. If they really loved nature in the full sense of the term, they could exercise their admiration within very narrow limits, and find in the same scenes perpetual stimulants to æsthetic curiosity. And they would be likely to content themselves within such limits because a special love for individual local beauties would result from long acquaintance with them.

In Mrs. Robbins' *Rescue of an Old Place* she rightly says that one great benefit which springs from the possession of

a few acres of ground is the development of a love for home, the suppression of that restless desire for change which makes so many Americans "possible tramps" instead of established citizens. But a genuine love of nature will serve a person pretty well in place of the actual ownership of a portion of the earth's surface. For in whatever corner of the country he may chance to be he will see, understand and love every part and phase of its beauty, and thus, in a sense, feel himself the owner of the whole region; and the oftener he visits it the stronger and more intimate will become his feeling of attachment to it. Of course, he will not be without a natural desire to see as much of the earth as possible, and to learn how many kinds of beauty it can show. But this desire will not be the imperative need for "a change" which is felt by less fortunately endowed persons, and often it will be so much weaker than his desire to stay among the things which he knows best, and therefore loves best, that year after year will pass, and foreign lands, or even neighboring regions, will tempt in vain while he watches new clouds blow over his familiar hills, the flowers spring up in his familiar woods, and every long-familiar shrub and tree assume a new aspect with each season's growth and changes.

This is the true secret of every kind of love; if a thing appeals to us at all, the better we know it the more we care for it. The true lover of nature loves it as the true lover of humanity loves men. He has his favorite corners of the world as he has his friends, and does not constantly wish to change them for others, or perpetually contrast their attractions with the attractions of others. If every one admires them his joy in them is increased; but if he is almost alone in appreciating their charm, this fact is in itself the source of a special kind of pleasure and pride. He seeks for novelty and freshness in the things which surround him as he likes his friends not to be all day and every day the same. He travels to new scenes in the same way that he likes to make acquaintance with interesting strangers, but comes back as gladly to the familiar spot as to the familiar face. The tree which he has watched as it grew from a sapling to a fine specimen delights him more than an even finer specimen about which no memories or anticipations cluster; and even if he has not planted and watered it himself, even if it grows in the neighboring forest instead of his own field, he has for it, nevertheless, a genuine personal affection. If he drives through a beautiful new country his eyes are perpetually charmed; but when he drives through the roads around his home his heart is touched and his imagination stirred by the beauty of past years as well as the beauty of to-day, and by the feeling that everything he sees is linked in some way with his personal experience. Each tree is a friend, each shrub has a special voice for his special ear, each flower is greeted as the child of other flowers which he knew last summer in the same corner of the road-side. In short, he not only admires what he sees; he is interested by everything he sees in a sense that is impossible where things are beheld for the first time. And true love, if it means admiration, means interest also, whether inanimate things or human beings are in question.

One who is truly interested in nature, therefore, does not need fine views in the usual acceptance of the term—great ranges of mountains, picturesque stretches of rocky coast, or outlooks over wide panoramas of hill and valley and river. Every view not seriously marred by some incongruous work of man has some charm for his eye. And he recognizes, moreover, that a very fine view must often be purchased at the expense of other attractions. If, for instance, there are mountains around him, he cannot have that far, low horizon-line which, stretching its mighty curve at a seemingly immeasurable distance, gives an unequaled sense of space, freedom and infinity. "I have never seen the sky before," a painter once exclaimed who had passed his life in hilly regions, and now, for the first time, stood in the low, quiet Cape Cod country; "I did

not know it was so big or so near or so arching, or that there were so many stars, or that a sight of them all could be so magnificent. I never before saw the moon come up from below the earth instead of merely from behind the hills, and I never saw the whole of a sunset until I came here." And he seemed to think that the panorama of the morning and evening and midnight skies was as admirable as any terrestrial panorama which could be unrolled before him.

Again, in our crude and often maltreated land, grandeur in the distance often means raggedness and forlornness in the foregrounds, and a sensitive eye thinks the foreground of a picture as important as its background. Where forests have ruthlessly been cut away, and where there is not a rich soil to encourage neat and careful cultivation, primeval beauty has largely vanished and the beauty of civilization has not replaced it. The true lover of nature will feel this painfully, and all the magnificence of the mountains beyond may not compensate him for the lack of that harmony and repose in general effect which come when all parts of a picture are in keeping. We do not say that the true lover of nature cares nothing for grand scenery, only that he does not actually need it. Great things impress him, but small ones enchant him, and he gathers pleasure from the road-side grass as well as from the giant Oak or the sky-line of a rugged mountain range. There is a beauty of the Lily and a beauty of the Pine, a beauty of the mountain and a beauty of the plain, a beauty of wide outlooks and a beauty of enclosed and sequestered corners. One kind of necessity excludes another kind; but that does not matter to him, for all arrest his eye, interest his mind, and make appeal to his imagination and his heart.

Notes of a Summer Journey in Europe.—XIV.

PROBABLY no city in the world can equal Paris in the beauty of its little parks and promenades, and more particularly for the wealth of flowers which is displayed throughout the summer in the flower-beds in these public places. But the exhibition of gayly colored exotics is sometimes introduced where a bit of pure nature would be a pleasant change. While such a fine show may seem appropriate enough in the Tuileries gardens, its effect is not altogether pleasing in such a place as the beautiful little Parc Monceau, where the formal flower-beds of glaring colors seem out of place among naturally grouped trees and shrubs.

But in spite of these inharmonious features the Parc Monceau seemed to me a charming model of a little city park. The situation is most favorable, and the trees and shrubs have for the most part been grouped with such good judgment and with such pleasant effect that, unlike most town parks of a few acres, one thinks of this as a country place, and not a garden in the heart of a city.

On the other hand, the famous Jardin des Plantes is likely to prove somewhat of a disappointment to most visitors. It may be that too much is expected, but the fame of the illustrious names which have been connected with this institution for nearly three centuries and the high order of scientific work which has been accomplished very naturally kindles the expectation of finding a botanic garden of the very highest order in every respect. Unlike some other botanical gardens, the Jardin des Plantes does not claim to be a popular institution, but prides itself on its scientific value. Therefore, in the purely scientific and systematic collections of living plants, no attempt is made to produce anything ornate. The greenhouses are not often freely open to the public, and there are some interesting collections not easy of access without special permits. If we find the garden inferior in some respects to what might be expected of it, from its age and fame and as the representative botanical institution of a great nation, it should be remembered that its situation and soil are not of the best, it has never been properly endowed by the Government, and, from all accounts, it suffered severely from the shells of the besiegers in the last great war.

The collection of living plants is undoubtedly one of the largest and most valuable in the world, but in many cases the specimens are not in a very thrifty condition. This, however, does not apply to the public floricultural display, which apparently receives much attention. Within the principal enclo-

tures, known as the "School of Botany," almost everything is planted in narrow parallel rows, which arrangement, although not so agreeable to the eye as a less formal and more scattered grouping, has the advantage of permitting perfect botanical sequence, so that one need not constantly refer to a plan in order to find particular groups of plants. In no large collection in a limited space can a classification in strict botanical sequence be perfectly satisfactory, because the trees will crowd and take from the soil what the neighboring smaller plants should have, and it is hardly possible to give each group the most congenial conditions of soil and exposure. The system of labeling is very complete here, the labels being of iron, neatly made, and the inscriptions in good distinct type. Indeed, there are more and better labels in proportion to the plants than in any scientific collection I ever saw. But, although the labels are so numerous and in such good condition, their inscriptions are not always to be relied upon as giving the correct name of the plant, and there is serious inaccuracy in the determination of species, certainly among some species from North America. To cite examples from our common eastern American Oaks: *Quercus alba*, *Q. macrocarpa* and *Q. nigra* are all represented as our Swamp White Oak, *Quercus bicolor*; a Red Oak has the Scarlet Oak label before it; *Quercus alba*, *Q. prinus*, *Q. prinoides*, *Q. coccinea* and other common American Oaks are not represented. *Betula nigra* is labeled *Betula lutea*, and the Canoe Birch (*B. papyrifera*) is passing as our Sweet or Cherry Birch (*B. leuta*). A long list might be made of instances like these, which shows that if the specimens are to have their intended educational value closer attention should be given to their names. Such mistakes are, no doubt, often caused by the stupidity of workmen, but when an establishment of such renown allows errors like these to pass unnoticed it is hard to blame nurserymen or commercial dealers for disseminating plants under wrong names. They might easily, and with some justification, give as an excuse that the plants were so named in the School of Botany of the Jardin des Plantes at Paris. A use of synonyms is perhaps more excusable, and we find this and other European gardens giving us credit for more species of such plants as Poplars, Ashes, Buckeyes, etc., than our botanists claim.

The garden contains many great rarities, and those persons who wish to see the most precious specimens and the very latest arrivals should seek admission to the very private little "pépinière," or nursery, which is crowded with interesting plants.

The visitor comes across old trees or trees of historic interest in various parts of the grounds of the establishment. The oldest tree of Paulownia in Europe is here, having been introduced in 1834, and now having a trunk six feet in circumference. The species has been planted in some of the squares, where it is kept cut back to a low broad shape, affording a dense shade, and apparently bearing pruning and the city atmosphere remarkably well. In a corner near the museum buildings is the aged specimen of our common Locust (*Robinia Pseudacacia*), which, the affixed label tells us, was introduced into France by Jean Robin in 1601, and that this tree was planted where it now stands by Vespasian Robin in 1636 (see GARDEN AND FOREST, vol. iii., p. 311). The trunk is now so much decayed that the tree can hardly live much longer. It has been patched up with plaster or cement, and the limbs are held together by iron rods. The Cedar of Lebanon planted by Bernhard de Jussieu in 1735 is apparently in as good health now as it could have been at that time, and it has a trunk about four feet in diameter. It is planted on a dry bank, just such a situation as should be selected for it in cold regions, so that its growth is not too rank. It seems surprising that attempts to grow and naturalize this tree in America are not more frequently made. Another plant of much interest is a specimen, now thirty years old and partly decayed, of the *Prunus Davidiana*, introduced from China by the celebrated traveler and collector after whom it was named. This plant has never fruited, a characteristic which has so far been followed by its grafted progeny at the Arnold Arboretum, where it is the very earliest of the Rose family to blossom, flowering this season as early as April 8th. The flowers seem perfect enough as regards stamens and pistils, and the non-fruiting peculiarity has been attributed to frost or cool weather at the time of blossoming, or, what may be quite as probable, to the lack of pollen from flowers of different seedling plants of its own kind. It is a question worth testing carefully. A little-known shrub or small tree of the Witch Hazel family is *Parrotia Persica*. A specimen of this here has several thick stems from the same base, is twenty feet high, and has a spread of thirty feet in diameter. It has proved quite hardy

in the vicinity of Boston, but as its flowers are not remarkable for any peculiar beauty, and it is chiefly valuable for the colors of its autumnal foliage, it is perhaps no more desirable from an ornamental point of view than some of our native Cornels and Viburnums. The flowers appear as reddish clusters of stamens in spring before the leaves.

The garden has been the medium through which many of the recently introduced Asiatic plants have been distributed, and it annually issues a long list of seeds of plants it has for exchange. While in some respects there are features about the garden which prove a disappointment, the herbarium and museum connected with it contain mines of wealth for the student in botany, and every one acquainted with the labors of Franchet and other students connected with it to-day recognizes the value of the scientific work still carried on within these unpretentious walls.

Arnold Arboretum.

Internal Decay of Forest-trees.

MY observations upon this subject, given in a recent issue of GARDEN AND FOREST, have brought me a large number of letters from many states, showing that the evil is a widespread one and difficult to account for. My own limited experience led me to infer that it might be due in some degree, if not wholly, to the situation of my woodland in a deep and narrow valley. I am not quite convinced that this is not the fact; but it seems evident from what I have gathered that this central decay of the trunks of forest-trees is not limited to such situations. Quite fortunately, in looking up another subject a few days since, I came upon the following, under the head of "Larch," in the Allen edition of the *Encyclopædia Britannica*. Here it is stated that the woolly aphid, or "Larch-blight," often attacks the trees in close valleys, but rarely spreads much unless other unhealthy conditions are present. But "a far more formidable enemy is the disease known as the 'heart-rot'; it occurs in all the more advanced stages of growth, occasionally attacking young Larches only ten years old or less, but is more common at a later period, when the trees have acquired a considerable size, sometimes spreading in a short time through a whole plantation. The trees for a considerable period show little sign of unhealthiness, but eventually the lower part of the stem near the root begins to swell somewhat, and the whole tree gradually goes off as the disease advances. When cut down the trunk is found to be decayed at the centre, the rot usually commencing at the ground and gradually extending upward. Trees of good size are thus rendered nearly worthless, often showing little sign of unhealthiness until felled." The writer of this article in the *Encyclopædia* adds that the manner in which this disease spreads indicates a fungal origin, and that some fungus mycelium may be the remote cause of the disease; but that "there is little doubt that any circumstance that tends to weaken the tree acts as a predisposing cause of the attack," and he thinks the best safeguards are probably perfect drainage and sufficient thinning. The writer of this article of the *Encyclopædia* is C. Pierpoint Johnson, editor of *Sowerby's Wild Flowers*.

But the most interesting letter which has come to me in this connection is from a well-known gentleman in New Hampshire, connected with the agricultural press. From this letter I make the following extracts: "I have often noticed in the woods in Maine, and in other places where I have had opportunity, this tendency to decay at the heart, although I never heard it discussed. It would seem possible that the location between wet and dry soils was the cause of the trouble. We know that the strip of land at the foot of a long slope, just before we come to a muck-swamp or a stream, is the hardest to convert into tillage land. A few inches of loose black scurf on a hard pan of white or rusty sand, when cleared it produces moss and running Blackberry-vines until Firs and Hackmetacks again come to the rescue. On my farm we cleared up a large meadow along a brook, and another in a dense swamp where the drainage was very slow, and the trees were so tall that we had to cut back some distance to get the shade off the grass land. On this border the trees were rotten at the heart. The White Maples and Black Ash and Elms and the other trees which were at home and sound on dry land, seemed to be affected on this strip. One Elm, about fifteen inches in diameter, had a shell about two inches thick; I sawed it off in sections and nailed on board-bottoms for feed-boxes. An Ash, with a shell about one inch thick, I split and made into troughs for feeding sheep. A Yellow Birch, with about three inches of shell, I made into a farm-roller." This writer thinks the interior rottenness in all these trees was probably due to the death of the tap-roots, from the unfavorable

nature of the soil, and the extension of the decay upward through the trunks of the trees.

Referring to the perfect soundness of the *Arbor-vitæ* trees of north-eastern Maine, previously alluded to by me, an item caught my eye in a recent copy of a Houlton (Maine) newspaper, as follows: "One of Aroostook's giant Cedars was cut by Geo. Humphrey's men at Thomas Taylor & Son's camp, on Cary Brook, last week. This Cedar was four feet on the stump, sixty-two feet long and ten inches in diameter at the top end—making 1,491 feet of inch-lumber."

Newport, Vt.

T. H. Hoskins.

Coontie and Conte.

THE article in GARDEN AND FOREST, of February 3d, 1892, on *Smilax Pseudo-China*, recalls an interesting bit of history connected with the botany of the south, which also brings forcibly to mind the difficulties in identifying a plant known only by a common name. I refer to the Coontie of the Florida Indians, the aboriginal name of *Zamia integrifolia*, the plant from which Florida Arrowroot is obtained. At first *S. Pseudo-China*, or some other species of *Smilax*, was supposed to be the Coontie, or Coontia, of the Indians. Dr. William Baldwin, one of the early investigators of the botany of Georgia and Florida, held this opinion. From 1812 to 1817 he was in this region collecting plants, and he seems to have been the first to identify Coontia with *Zamia*. Dr. Henry Muehlenberg, his constant correspondent, shared these doubts about the Coontia, or Bread-plant, of the Seminoles. This correspondence was published by Dr. William Darlington, in *Reliquiæ Baldwinianæ*, and in a letter dated June 18th, 1812, Muehlenberg asks Dr. Baldwin, "What is the real Coontie of the Indians? Is it *Smilax laurifolia*, or do you find it figured in Catesby or elsewhere?" Baldwin replies: "The root which furnishes the Coontia of the Creeks is certainly *Smilax*."

Five years later, after Dr. Muehlenberg's death, he found the real Coontia south of St. Augustine, and in 1817 he writes to Darlington: "Here, in a thin sandy hammock of small Live Oaks, Cabbage and San Palmettoes, I had the gratification to find the 'Wild Sago,' or Coontia, of the Seminoles, and to assign it its place in the sexual system—*Dioicia*, *Polyandria*, natural order *Palmæ*. I have no books with me to refer to, but it is probably a new genus, approaching very closely in habit to the real Sago family (*Cycas*). At supper I had the pleasure to eat the bread prepared from the large tuberous root of this plant. . . . I have no hesitation in saying that it will be found among the most important of our Esculentia." A few days later he writes: "I now find that my Coontia, or Wild Sago, is nothing more nor less than *Zamia pumila*—that is, *Z. integrifolia*, Willd. Dr. Baldwin therefore traced the Coontia of the Seminoles, whatever may have been that of the Creeks, to *Z. integrifolia*."

Referring to Bartram's Travels (English edition, page 160), and the only place where much is said of it, there is no allusion to its use as food, but to its beauty alone. As Bartram was particular in his observations, this seems strange, and may indicate that he was unacquainted with such a use of *Zamia*. Subsequently he went to an Indian village, perhaps not far from Appalachee Bay, and in middle Florida. Here he was entertained by the Indians, and partook of a dish which he calls conte (contee in the table of contents), and of which he writes (*ibid.*, 239) quite minutely: "Early in the morning our chief invited me with him to take a final leave of the White King. We were graciously received and treated with the utmost civility and hospitality; there was a noble entertainment and repast provided against our arrival, consisting of bear's ribs, venison, varieties of fish, roasted turkeys, hot corn-cakes, and a very agreeable cooling sort of jelly, which they call conte; this is prepared from the root of the China-brier (*Smilax pseudo-China*; *S. aspera*, fructu nigro, radice nodosa, magna, lævi, farinaacea; Sloan, *Nat. Hist. Am.*, i., p. 231, t. 143, f. 1; habitat Jamaica, Virginia, Carolina and Florida). They chop the roots in pieces, which are afterward well pounded in a wooden mortar, then being mixed with clean water in a tray or trough, they strain it through baskets; the sediment, which settles to the bottom of the second vessel, is afterward dried in the open air, and is then a very fine reddish flour or meal; a small quantity of this mixed with warm water and sweetened with honey, when cool becomes a beautiful, delicious jelly, very nourishing and wholesome. They also mix it with fine corn-flour, which being fried in fresh bear's-oil makes very good hot cakes or fritters."

A question of interest is suggested by this quotation, whether this agreeable food, conte, of these Indians (called Lower Creeks as well as Seminoles by Bartram) is the same as the

coontia of the Creeks and Seminoles mentioned in the letters of Muehlenberg and Baldwin. There is a similarity in the names, which may be a matter of etymology—of words coming from the same root and indicating a food-product of analogous use. But this does not necessarily make them identical. Though not, perhaps, too far north for the growth of *Zamia* (if the conte was derived from a local plant), since Bartram on the third day of his return from this village to the St. John's speaks of gathering seeds of *Zamia*, it would hardly seem that one mentioning *Smilax* so definitely as the source of conte would confound it with another plant. Then he must have been well acquainted with *S. Pseudo-China*, which he mentions elsewhere, and which was a common plant from New Jersey to the Gulf of Mexico, a region through which he passed more than once.

Is there, then, in the large tuberous roots of this *Smilax* a food worthy of the attention of those in quest of new native sources of food-supply? How valuable might it be if used as an esculent, and improved by cultivation like most of the vegetables which come to our tables. Animals are well aware of its edible properties, for pigs root up the ground for the tubers, a fact also noticed by Pursh in his *Flora*. Its useful qualities were also known to other botanists. Elliott, in his *Sketch of the Botany of South Carolina and Georgia*, does not mention it as an esculent, but says of it: "This species forms the basis of many 'diet drinks' among the 'unlicensed faculty.' From the roots, with Indian corn, sassafras and molasses, the negroes manufacture a very pleasant beer." Rafinesque is more explicit. In his *Medical Flora* he says of *Smilax*: "All more or less equivalent. *S. Sarsaparilla*, best known; *S. Pseudo-China*, largest roots, extend one hundred feet in damp soils, forming clusters. Much used by the southern Indians for food, mush, and the fecula is a red-brown flour. Good beer made with sassafras and molasses purifies the blood. Shoots eaten like asparagus. *S. caduca*, *laurifolia*, *tamnoides*, etc., equally used." Having mentioned their medical properties, he concludes: "Properties reside in the bark containing pariline, fecula, mucus, albumen. The centre is pure fecula, inert, esculent."

Foreign Correspondence.

London Letter.

THE meetings of the Royal Horticultural Society in April and May are invariably of more than ordinary interest. The last one was remarkable for the numerous examples of well-flowered specimens and rare Orchids, Anthuriums, Hippeastrums and other stove-plants, hard-wooded greenhouse-plants and hardy flowers. The Orchids included a group of the noble *Dendrobium Phalænopsis*, var. *Schroederianum*, from Messrs. Sander & Co., showing even greater variety in color than we have hitherto seen, besides extraordinary size and vigor of growth. Already one can see that this *Dendrobium* promises to be one of the very best of tropical Orchids. From the same firm came plants in flower of the new *Cypripedium Chamberlainianum*, which was unanimously awarded a first-class certificate by the Orchid committee. It is rich in color, peculiar in form, and, while scarcely deserving to be placed among the very best of the *Cypripediums*, it can hardly fail to rank high as a garden plant if it only proves amenable to ordinary cultivation. *Masdevallias* included the pretty hybrid *M. Courtauldiana*, which is now flowering at Kew, and the rare little *M. Wendlandiana*, interesting as being the only known tropical species of *Masdevallia*. At Kew it grows and flowers freely in the East India-house. Messrs. Hugh Low & Co. contributed a group of choice Orchids, chiefly *Cattleyas*, *Odontoglossums* and *Vandas*. They also sent the delightful little *Angræcum fastuosum*, the large *A. sesquipedale*, beautiful though somewhat out of season, and the dainty little *Saccolabium bellinum*, which is a specialty at the Clapton Nurseries. Messrs. B. S. Williams & Son sent numerous *Vandas*, *Dendrobium Wardianum* and the large-flowered variety of *Cochlioda vulcanica*, recently introduced and named *grandiflora*.

The importance of these periodical exhibitions held by the Royal Horticultural Society in London is testified to by the frequent contributions which come from Continental

gardeners. Messrs. Linden sent to this meeting from Brussels some beautiful *Odontoglossums*, including *O. Pescatorei*, var. *Lindenizæ*, which has large purple-spotted flowers, and another variety, also purple spotted, named *maculatum*. *Odontoglossums* are cultivated better in Brussels than I have seen them anywhere, and the nurserymen there are fully alive to this. I believe Mr. Linden never misses an opportunity to acquire plants of the choicest and most valued varieties with a view to their multiplication. Messrs. Veitch & Sons sent *Dendrobium atrovioleaceum* and several hybrids, including one raised from *D. Pierardii* and *D. superbum*, which they call *D. Adrasta*. It has soft pink sepals and petals and a pale yellow lip.

The amateur exhibitors were led by Sir Trevor Lawrence, who sent *Cypripedium Elliotianum* with eight flowers, a beautiful example of good cultivation, and a hybrid called *C. lawrebelleum* (a ridiculous name, pure Choctaw to outsiders!), which is the result of crossing *C. Lawrencianum* and *C. bellatulum*. The flowers are in form like those of the first-named parent, their color being rosy crimson with brown-purple lines, the dorsal sepal margined with white, and the petals spotted with chocolate.

From Mr. H. J. Elwes came a grand specimen of *Vanda Denisoniana*, with a cluster of healthy growths bearing no fewer than eight spikes of large milk-white flowers. *Dendrobium primulinum* was shown in exceptionally fine form. Several beautiful varieties of *Miltonia Roezlii*; the distinct Siam variety of *Cypripedium insigne*; *Cattleya Marriottiana*, a hybrid between *C. Skinneri* and *Lælia flava*; the magnificent *Odontoglossum Leeanum*. These and many other rarities were conspicuous among the various groups which crowded the exhibition hall.

Cliveas were well shown by Messrs. B. S. Williams & Son, and also by Messrs. J. Laing & Sons, both firms making a specialty of these plants. *Hippeastrums* were represented by *Crimson King* (Veitch) and *Firebrand* (G. Paul & Son), both awarded certificates. There were also large groups of these plants from other nurserymen.

Magnolia conspicua, the Yulan *Magnolia*, was shown by Mr. Hudson, gardener to Messrs. Rothschild at Gunnersbury House, Acton, where there is a specimen of this noble *Magnolia* thirty feet high and as much through, and which at this season of the year is always a magnificent picture of snow-white flowers. *M. stellata* (Halleana) was shown in flower, the type, a rose-tinted variety and a double-flowered form. At Kew this little species is grown in a round bed on a lawn, where it forms a pretty mass eighteen inches high. It is quite hardy here. It also does well when grown in pots and slightly forced for the conservatory. *Rhododendron campylocarpum*, a hardy species from the Himalayas, with large trusses of large yellow flowers, was shown by the Exeter Veitchs. I may note here *R. fulgens*, also Himalayan, which is now in full flower outside at Kew among the hardy *Rhododendrons*. The plant is probably forty years old, and it is now crowded with heads of the richest rose-crimson flowers.

Roses, some of them new; *Ericas* of various kinds, the most conspicuous being *E. ventricosa coccinea* and *E. Cavendishiana*, *Epiphyllum Makoyanum* and *E. Gärtneri*, both varieties of one species, which was recently figured in the *Botanical Magazine* under the latter name. A *Cineraria* named *Snowflake Improved*, with the flowers wholly white, came from Messrs. J. Carter & Co. It will be a useful plant if its character can be fixed so as to come true from seeds.

Daffodils. There was a special exhibition of these plants, with a special committee to award prizes and discuss the merits of new kinds. The programme for the day also included a lecture on *Narcissi* by the Rev. G. P. Haydon. It is scarcely possible for any one nowadays to say much that is new about Daffodils, to English growers at any rate. The lecturer traveled along the beaten track, and gave good advice to amateurs and beginners, for whom his remarks were specially intended. He suggested that flower-collectors should be compelled to carry a license

similar to a game license as a preventive to the destruction of wild flowers, which at present were being totally eradicated from some localities by the vandal flower and plant collector, who often dug up by the bushel rare plants which could not possibly survive the treatment they got.

London.

W. Watson.

Plant Notes.

The Narcissus.

NOW that the *Narcissus* season is here, it may be interesting to note the distinguishing characters of the groups into which this family is divided, and give in a compact form the main points of their structures as a guide to a more careful study of these ever-welcome flowers. The popular name of Daffodil, which is generally used in the garden, is only correct as applied to two forms of *Narcissi*—i. e., the *Narcissus Pseudo-Narcissus*, the flat-leaved or Trumpet Daffodils, and *N. Bulbocodium* (*Corbularia*), Hoop Petticoat or Rush-leaved Daffodils. In other words, Daffodils are *Narcissi*, though only the large-crowned *Narcissi* are Daffodils. A *Narcissus*-flower is structur-

Fig. 32.—*Narcissus cyclamineus*.

ally composed of an ovary, the perianth-segments (popularly the saucer), and the tube, otherwise called the crown, the trumpet, the trunk or corona. An inferior ovary is situated at the base of a cylindrical tube. From varying localities along this tube spring the perianth-segments, and beyond these the cup is prolonged. In the Daffodils the six stamens are of equal length, and have the same point of insertion low down near the obconical-tube. In the true *Narcissi* the tube is much longer, narrower and cylindrical; the six stamens are divided into two sets of three each, which are inserted, one set near the mouth, and the other three midway between the crown and ovary.

The varieties of *Narcissi* are endless and beyond the ken of man, and authorities are not yet agreed as to the number of distinct species. Mr. J. G. Baker, of Kew, published in 1869 a clear and concise system of grouping, which has been generally adopted by growers and by the trade. Mr. Baker's groups are based on the length of the perianth-segments as contrasted with that of the cup. The three groups of Baker are:

GROUP I. *Magnicoronati*, the large cup.

GROUP II. *Mediocoronati*, the medium cup.

GROUP III. *Parvicoronati*, the small cup.

Each of these groups is divided into sub-genera, species and sub-species; but for the non-botanical reader and cultivator it will be simpler and sufficiently clear to divide the groups according to the plan of Mr. F. W. Burbridge, of Dublin, into two sections—A, the flat-leaved kinds; and B, the rush-leaved kinds. Under this arrangement we give the different sections with an illustration of a typical flower of each:

GROUP I. Large cup, crown as long or longer than perianth.

Section A. Flat-leaved. Type, the wild Daffodil of England, and including *N. Pseudo-Narcissus*; the Ajax varieties of Ha-

Fig. 33.—*Narcissus maximus*.—See page 209.

worth, and innumerable forms and sizes from *N. minimus* to *N. maximus*. All have flat glaucous leaves. The better-known garden forms of this section are—Yellows: Ard Righ, Countess of Annesley, Cyclamineus (fig. 32), Emperor, Golden Spur, Henry Irving, Maximus (fig. 33), Minimus (fig. 34), Obvallaris (Tenby), Rugilobus. Two-colored varieties: Empress, Grandis, Horsfieldii, Princeps, Scoticus, Bicolor præcox. White and sulphur varieties: Cernuus (fig. 35), Colleen Bawn, F. W. Burbridge, Minnie Warren, Moschatus, Pallidus præcox. Double: Telamonius plenus (Von Sion), Capax plenus.

Section B. Rush-leaved. Type, *N. Bulbocodium* (Corbularia), the Hoop Petticoat Daffodil of southern Europe. Of these there are six varieties, all with the expanded crinoline-like corona (fig. 36).

GROUP II. Crown half or rarely three-quarters as long as the perianth divisions; the Chalice-shaped crown of Parkinson.

Section A. Type, *N. incomparabilis* varieties (fig. 37). The varieties of this group are supposed to be hybrids, except Odorus, Juncifolius and Triandrus. Garden forms of these comprise: Self-yellow varieties. Yellow varieties with orange cups; Gloria Mundi, etc. Sulphur-colored varieties; Sir Watkin, etc. Peerless varieties; Cynosure (primrose perianth, orange cup), Princess Mary (white perianth, orange cup). White varieties; Mary Anderson, etc. Leedsii varieties, with Eucharis-flowered chalice, cup white; Leedsii, Amabilis, Duchess of Brabant. Humes' hybrid straight-crowned Daffodils. Backhouse's hybrids with coffee-cup-shaped crown. Nelson's hybrids with goblet-shaped cup; Nelsoni major, Aurantius, Pulchellus. Double varieties; Aurantius plenus (Butter and Eggs), Albus plenisaurantius (Orange Phœnix), plenus sulphureus (Codlins and Cream or Sulphur Phœnix).

Section B. Types, *N. Odorus* (Campernelle Jonquil), *N. triandrus* (fig. 38), *N. juncifolius* (the smallest Rush-leaved Daffodil).

GROUP III. The small-crowned Daffodils or true Narcissi.

Section A. Types, *N. poeticus*, *N. Tazetta*. In this section are comprised the well-known *N. poeticus*, also the various bunch-flowered Daffodils, as Paper Whites, Grand Monarque, Soliel d'Or, Staten General, etc.

Section B. Types, *N. gracilis*, *N. rupicola* (fig. 39), *N. Jonquilla*; the Jonquils are the best-known form of this section.

A review of the genus *Narcissus* to 1887 is embodied in Baker's *Handbook of the Amaryllideæ*, 1888; Burbridge's *History and Culture of the Narcissus*, published in 1875; *Ye Narcissus or Daffodil*, by F. W. Burbridge and P. Barr; and Hartland's *Album of Daffodils*, will all prove useful to those interested in the study of this genus.

In this climate the flowering of Narcissi is influenced by so many sudden changes of temperature that it would be impossible to give any definite or even general idea as to the succession of flowers to be expected with any certainty. As to the varieties the Ajax section comprises the largest number of favorites, a good selection being for garden purposes Emperor, Empress, Horsfieldii, Grandis, Obvallaris, Golden Spur, Maximus, Countess of Annesley, Ard Righ, Rugilobus, Cernuus, Pallidus præcox and Telamonius plenus. A fine selection from the other sections, omitting Polyanthus, is Sir Watkin, Barrii conspicuus, Duchess of Westminster, C. J. Backhouse, Princess Mary, Poeticus ornatus, Gloria Mundi, Cynosure, Nelsoni, Poetarum, Poeticus plenus, Orange Phœnix, Capax plenus.

Elizabeth, N. J.

J. N. Gerard.

Cultural Department.

A Selection of Strawberries.

THE list may now be fairly divided into early, medium and late. Crystal City till recently was our best very early. Michel's Early did not prove to be what was hoped for and promised; the berry lacks quality, and the plant productiveness. Beder Wood is, on the contrary, a really good berry, very productive and of good size. Mr. Crawford thinks it the best very early berry that he has yet grown. Leader has secured three prizes from the Massachusetts Horticultural Society. It is a very early sort, and, I believe, is destined to secure the very foremost place. Lovett's Early is another new candidate of great promise. It is said to be larger than Wilson, and more prolific than Crescent. The color is bright crimson and the shape perfect, while the flavor is high. It gave ripe berries last year on the 22d of May in New Jersey, which is something remarkable. It is almost as early as Crystal City, and we may, therefore, expect to discard that inferior fruit very soon. What we have wanted was a good market and table fruit as early as Crystal City. We can confidently plant Leader and Lovett's Early and Beder Wood.

Of medium berries Cumberland comes so close after the early as to deserve a mention at the head. It is an old sort that very few are willing yet to discard. Mrs. Cleveland is, on the whole, one of the best berries I ever raised. It is large, but not largest; good flavor, not the best; brilliant in color, and enormously prolific. It begins early and bears long. Among forty new varieties I hold Mrs. Cleveland one of the very best. Crawford has very large and excellent berries, but it has not proved regular in size or as prolific as Mrs. Cleve-

Fig. 34.—*Narcissus minimus*.—See page 209.

land. Haverland is splendid when the season is not too wet, but it is sometimes watery and soft. The berry is of the largest size, and of good, but not the best quality and color. Gillespie, a seedling of Haverland, bids fair to outstrip it. One of the

most wonderful berries in my trial-beds has been Thompson's 51; it is not yet introduced. It is big enough for a pear. Lida I reckon among the best, and it should not be discarded for new favorites. Bubach is among the leading sorts, but it

Fig. 35.—*Narcissus cernuus pulcher*.—See page 209.

has a pistillate flower. Edgar Queen is a monstrous berry of excellent quality. The fruit of Saunders is finely shaped, very large, and of a fine glossy red. The flesh is also red, and the flavor fine. Pearl I have always liked. The plant is a capital grower in a large stool, while the berry is both handsome and excellent. Enhance is probably ahead of all in cropping, but not in quality. It is an enormous berry, not always well shaped. Parker Earle is remarkable for the favor it has received in widely separated regions north and south. The berry is of fine size, not largest; long and necked, firm and handsome, and an extraordinary cropper. It is almost late enough to be classed in that list rather than as medium-early. Warfield and Crescent I reject, as I do Wilson, because they are too sour for a good home berry. As shippers they are, of course, good; but there are just as good shippers that are much larger and sweeter, and I am quite of Mr. Terry's opinion, that it does not pay to grow berries that do not average large. The time lost in picking is great, and in market the biggest are always in demand; the others are often not wanted, and must sell at low figures.

Of the late sorts Manchester is old, but still good, only a little too tart. Yale is winning its way as a really first-class berry, and extra for canning. It is solid and dark red, and colors finely in the can. The quality is of the best. Gandy has some strong friends, but many report it as not sufficiently prolific, which is about the truth of the matter. A new berry is being pushed as something remarkable, and remarkably late—the E. P. Roe. It certainly is very late, the last fruit having reached market about the middle of July. It resembles the old Kentucky, and will bear testing before much planting.

I have not mentioned in the list of main croppers Bubach with sufficient emphasis, because I do not yet see one berry that should crowd this out; and as for Sharpless, which should be ranked almost with the late, it is with me invaluable for quality, and good for quantity. Others do not find it to have either of these qualities. My soil is clay, and moist. It seems very probable that Beverly will prove one of the principal rivals of the Bubach and Sharpless. It has received a large number of prizes and has a perfect flower, while Bubach is pistillate.

It is impossible to make out a list of Strawberries for the whole country and for all soils. Cumberland and Bubach have come as near as any to being universal berries. I grow my berries on an eastern slope, a warm soil for clay, and keep it well fed. I plant in hills, and let them run into matted rows after the first year's good crop. The best time to plant is invariably very early in the spring.

Clinton, N. Y.

E. P. Powell.

Flower-garden Notes.

THESE are busy times in the hardy flower-garden; all protective coverings have been removed, and plants are coming up vigorously. No time should be lost in moving plants now, as the less growth they make before they are planted the more certain the success the coming season. Some plants never do so well as when planted while small where they are to remain, and I am convinced that this is one of the secrets of success with that beautiful Columbine, *Aquilegia glandulosa*. Many people prefer large plants, and it must be admitted that, in some cases, they are desirable, but many of the more robust sorts, such as *Delphiniums*, *Campanulas*, *Aquilegias* and *Phlox*, grow with greater vigor if they are transplanted when small. The first flower in the garden this season was *Primula denticulata nivalis*, the white form of a well-known Himalayan Primrose. The spikes of flowers come before the foliage, as in *P. rosea*, and are pure white, with a yellow eye. These were raised from seed a year ago and planted in a shady corner in a group with *P. rosea*, which is now also in bloom. The typical *P. denticulata* is also perfectly hardy, and the flowers are lilac-colored. *P. cortusoides* is also in flower, and is a pretty little species, often said to be the same as *P. Sieboldii*, but there is a vast difference from a garden standpoint, the last-named plant being much better, the numerous varieties making a charming group in themselves. We are so accustomed to seeing *P. Sieboldii* grown indoors in pots that we are apt to forget how well it thrives outside in a shady moist situation if slightly covered in winter, as the roots are rhizomatous and easily lifted by frost. Those who possess a rock-garden would do well to try these Primulas, selecting for them moist shady nooks. The sun in summer is more distressing to them than the cold of winter.

Auriculas are now in full beauty in cold frames. These are so easily managed in this way that they ought to be taken up by many who can afford a frame in a shady place in summer. A bunch of *Auriculas* when cut makes a sweeter and prettier nosegay than almost any other Primrose. The old-fashioned double white Primrose has been in bloom more than a month, and is now turning pink, but it has been in bloom in good condition for a longer time than usual with Primulas. This was wintered with the *Auriculas*, and is very easily propagated by division; seeds are not produced.

The long-continued dry weather is somewhat unusual at this season, as we have had no rain for four weeks, and the consequence is manifest in the *Narcissus*-beds; the flowers are coming short-stemmed, and water is sadly needed at the roots. This season, as last, *N. bicolor præcox* was in bloom a week before any other kind, and a few days ago it was the only kind in bloom but *Ard Righ*. *N. obvallaris* and *Golden Spur* soon followed, and we have now over a dozen kinds in full bloom.

Fig. 36.—*Narcissus monophyllus*.—See page 209.

There is a great future for *Golden Spur* and *Countess of Annesley* (the *Castlewellan Daffodil*), the last being especially free-blooming and vigorous, increasing threefold annually. By the time this is published the best kinds will all be in bloom.

Salvia argentea is a plant usually grown as an annual for the beauty of its foliage, and in the early part of the day when sparkling with dew it presents a pretty picture in the front row of a border. It was a surprise to see plants set out last year

Fig. 37.—*Narcissus incomparabilis*.—See page 209.

coming up strong and unharmed by the winter, as there are no other *Salvias* that will live out unurt in this locality, and even the garden Sage has to be treated as an annual. Every spring one is tempted to ask why *Mertensia Virginica* is so seldom seen in gardens, since there is nothing more beautiful in its season. It is very plentiful and easily obtained in some sections, but rarely seen in gardens. The beautiful blue flowers last well when cut.

South Lancaster, Mass.

E. O. Orpet.

Flowers in Bloom.

AMONG the flowers now in bloom is a distinctly colored Grape Hyacinth, named *Muscari Scovitzianum*, and a valuable addition to this interesting group. The long, prostrate leaves were produced in early winter. The flowers appeared in middle April. The flowers individually are rather small, but are of a beautiful opaque, pure blue, with no trace of purple, and with a white rim. Single bulbs have thrown three spikes of flowers. This would be a fine variety to associate with *M. botryoides alba*, whose pure white flowers are now in their prime. *M. Scovitzianum* is an introduction of Herr Leichtlin, as is also

Fritillaria Dalmatica, an interesting but not showy plant. The flowers are bell-shaped and single, on stems about six inches high, and droop gracefully. The petals are green outside, stained brown, and inside a deep brown, mottled and stained with green. In suitable positions, the dwarf and small-growing *Fritillarias* are interesting garden-plants, better adapted to the rockery than an open position, however.

The charming hybrid Primroses, with their bright flowers shining over a background of tender foliage, are among the choicest of the flowers of the season, and of the easiest culture. With me they prove very reliable, perfectly hardy in winter, and not burnt up by summer heat. I have before mentioned that they do well in my garden on a raised border, a few feet from the south side of the house, where it is often very warm. My friends at a distance, with some experience of Primulas, often express what I may perhaps call polite surprise at this fact. But it is only another indication that in our various gardens we have quite varied experiences. On my part, I do not know how others establish Primroses in grass, as one sees frequently noted and advised. In such cases it would be interesting to know what variety of grass is found suitable for the association. My garden being surrounded by vacant land, we are supplied with a large assortment of grasses, and apparently all of these, without exception, grow vigorously enough (outside of the lawn) to strangle anything but the most vigorous plants. My border of hybrid Primulas,

seedlings three years old, is of a vigorous strain (Dean's), but has been neglected. The crowns have not been divided and are much crowded. Where the grass had been taken out they are still vigorous, but most of the plants this spring were overcrowded with grass, and were rapidly becoming exterminated. Another strain of Primroses, not far removed from *P. veris*, shows even less vigor when attacked by grass. *P. elatior* (*Polyanthus*) has also largely disappeared under its encroachments. Primulas should, no doubt, be divided every second year at least, and given good culture, as they are gross growers and increase rapidly.

Auriculas are other members of the *Primula* family, now gradually showing their beautiful flowers. These alpine Primulas are kept under glass, to protect the meal from wet and to preserve the purity of the blooms. Choice Auriculas come under the head of precious flowers, and are well worth the care which they undoubtedly require. While they are hardy one does not care to plant out any but varieties discarded from the collection as not being first-rate, the others being kept always in pots or planted in a frame under shelter.

This is one of the oldest favorites of the florists' flowers, and the small but devoted band which makes them a hobby in England seems to me the most interesting group of flower fanciers. An Auricula fancier discusses the points of his favorite with an old-time ingenuousness and such a flood of reminiscences that one heartily enjoys his amenities and enthusiasm, while not caring at all whether the paste and the eye of the flowers are in proper proportion.

One of the Squills lately sent from the Taurus mountains is a variety of *Scilla bifolia*, named Whittall in honor of its collector. This variety is quite distinct, the leaves being more numerous than in the type, and channeled. The flowers are borne in long racemes and are upright. Individually they are small, with narrow petals, and somewhat resemble *Chionodoxa Sardensis*. The first sample of these, received in 1890, flowered earlier than the lot from a later collection.

A few lingering flowers of *Anemone blanda* remind me to say that though this valuable plant is perfectly hardy, it evidently has a choice as to suitable position. It does much the best with me in a warm snug corner, protected on all sides but the south, and where it is baked all summer. In this position it came into bloom in January, the tubers having been undisturbed for three years. Mr. E. Whittall sent me for trial last fall a large lot of what was said to be a finer and more robust form, *A. blanda robustus*. The tubers of these have not

Fig. 38.—*Narcissus triandrus*.—See page 209.

been so happily placed, being in colonies in more exposed positions, and though, as was to be expected of newly collected pieces, not flowering freely, yet they seem still more affected by being planted in exposed positions. Such flowers

of this variety as have appeared give indications of being very handsome. Herr Leichtlin's varieties, *A. blanda alba* and *A. blanda Cypriana*, have also, in exposed positions, confirmed the

far been very cool, and *Scilla Sibirica* and *Chionodoxa Lucillæ* have been in fine condition for a long time. One or two hot days will finish them.

Wellesley, Mass.

T. D. Hatfield.

Fig. 39.—*Narcissus rupicola*.—See page 209.

conclusion stated, that protection and subsequent baking are desirable for these plants.

Elizabeth, N. J.

J. N. Gerard.

***Campanula pyramidalis*.**—Contrary to expectation this plant has proved quite hardy here where the commoner *C. Medium* died. It is one of the very best for pot-culture, having a compact self-supporting habit. Compared with the Canterbury Bell the flowers are small, but they make up for their lack of size in number. They come into bloom early in June, and are very useful for standing on steps and about entrances of residences.

Although a true perennial, when grown in pots it is better treated as a biennial, as excessive blooming destroys the symmetry of the plants, so desirable when grown as specimens. Seeds sown in spring will produce fine crowns for potting into nine-inch pots in the autumn. It is better to store the plants in a frost-proof pit, otherwise they will lose their lower leaves, and look leggy. As single specimens in a rock-garden this *Campanula* serves in a charming way to break up the monotony so often noticeable where nothing but low-growing herbaceous or alpine plants are used. For this purpose the white variety is the more effective.

***Alstroemeria pelegrina*, var. *alba*,** the "Lily of the Incas," is described in European catalogues as tender, and it is further recommended that "a warm spot be selected for it." The further my observation goes the more I am convinced that the test of hardiness is not in proportion to the lowness of temperature. This plant has proved quite hardy here for two winters, even in exposed situations. It will be fortunate if this lovely Amaryllidaceous plant should prove quite hardy, being an excellent subject both for border and cutting purposes. Plants come quite easily from seed or by division of the roots.

Medinilla magnifica is now in bloom in the tropical plant houses belonging to H. H. Hunnewell, Esq., Wellesley. It comes from the East Indies, and was once commonly grown, no collection of flowering stove plants being considered complete without it. It is gorgeous when in bloom, with long verticillate, drooping panicles of pink flowers; the appendiculate anthers, a character peculiar to all Melastomaceæ, are strikingly conspicuous. When out of bloom it is a very ungainly shrub, very subject to insect pests, particularly the mealy bug.

Primula rosea is very bright this spring. It easily loses color, and is past very quickly if the weather is unseasonably warm, as is often the case during April. This spring has so

The Forest.

The Forests of California.

AT the last meeting of the American Forestry Congress, Hon. William Alvord, the president of that body, read a paper on this subject, from which we make the following extracts:

There is much about the silva of California that is broadly distinctive, and not met with in any other part of the world. Some of the trees are larger and probably older than any found elsewhere, except perhaps among the Eucalypts of Australasia, and they are not confined to small groups or belts, but are in great forests, some of which cover areas nearly as large as the whole of New England. There are millions of trees any one of which would yield enough lumber to build a good-sized house. Twenty millions of acres of California are covered with magnificent forests; the remainder is sparsely wooded or wholly treeless.

The heavily timbered districts are confined to the Sierra Nevada mountains on the east, the mountainous regions in the northern half of the state, and what is known as the Redwood belt, lying along and adjacent to the north-western sea-coast. The heavily timbered portion of the Sierra Nevada covers a territory five hundred miles long by seventy wide; the Redwood belt and the timbered mountains at the north comprise nearly half as much more. The whole aggregates about 50,000 square miles of lumber-producing forests for the entire state, which contains 158,000 square miles.

There occur in other sections of California patches of lumber trees, the most important of these being in the Central Coast Range and in the San Bernardino and Kingston mountains; the product of the latter, situated in the desert regions of the south-east, is more valuable for fuel than for building material. The inferior growth consists mainly of several varieties of Oak and Pine, with some Madroña, Maple, Walnut, Alder and Ash; the Sycamore, Willow and Cottonwood grow along the water-courses and in other moist localities. The few trees that grow in the desert-lands in the south-eastern angle of the state are the Mesquit, Palm and the Paloverde; the Palms, of which there are several varieties, are almost worthless, being alike unfit for fuel or lumber, and they do not bear edible fruit nor furnish shade. These and the Cactus are signs of aridity and barrenness.

The chain of mountains which skirts the easterly border of the state has an average height of about 8,000 feet, with long stretches much higher, some of the peaks attaining an altitude of 14,000 feet. The Piedmont country on the west, which attains an elevation of about 2,000 feet, and varies in breadth from fifteen to twenty-five miles, is covered with a sparse growth of scrubby Oaks and Pines; at the upper edge of the domain the more stately and valuable forest begins. While the foot-hill Oaks are of several kinds, the Pines are mostly confined to a single variety, the *Pinus Sabiniana*, called by Californians the Digger or Nut Pine. The last name is given it on account of its edible nut, which constitutes one of the staples of subsistence of the Digger Indian. The Nut Pine, though little fit for lumber, makes a fuel nearly equal to Hickory, and serves tolerably well for mine-supports. Mingling with the Oaks and Pines are various dwarf trees, also much shrubby, chiefly the Ground Oak, Chemisal, Buckeye and Manzanita. These are worthless save for firewood, and they are being cleared off in many places since the ground is found to be excellent for fruit-trees, and many orchards are being set out here.

Leaving the Red foot-hills we enter the zone above, with its steeper acclivities and its wondrous wealth of woods. While nearly all that is valuable consists of conifers, there are Oaks and many other deciduous trees in considerable numbers up to a height of 7,000 or 8,000 feet; also the Nut Pine up to 4,000 feet. This is the only conifer that does not thrive at a higher level.

While there is considerable shrubbery at these levels, the forests are so little obstructed with undergrowth that a wagon can be driven through them almost everywhere without much trouble. The woods lower down are still more open. The forests in this higher zone take in nearly the entire cone-bearing family, the Pine, Spruce, Fir, Cedar, Juniper and Cypress being represented, and they thrive in all latitudes and levels

up to about 9,000 or 10,000 feet. Above this the trees dwindle in size and the wood deteriorates in quality. At about 12,000 feet of altitude vegetation ceases, the mountains above are of naked granite and mostly covered with snow all the year round. In the high and heavily timbered lands the conifers are represented by fourteen genera and fifty-two species, there being sixteen or more species of Pines, all somewhat different from their eastern congeners.

After leaving the foot-hill country the first of these majestic trees encountered is the Yellow Pine (*Pinus ponderosa*), a tree of most noble presence. It is widely disseminated from central Oregon south to Mexico, and laterally from the Coast mountains east, across the cascade and the Sierra Nevada ranges. In size and in value for lumber it ranks next to the Sugar Pine, which comes in a little higher up. In the mountains lying toward the sea, as also in the arid interior, the Yellow Pine is considerably smaller, but on the Sierra it attains a height of two hundred to three hundred feet and a diameter of ten to fifteen feet. It is among the best of our timber-trees, the wood being soft yet firm and unusually heavy. A greater amount of lumber is made from it than from any other tree in the Sierras.

At an elevation of about 3,000 feet the Sugar Pine (*Pinus Lambertiana*) begins to appear; its best development is reached at about 5,000 feet, and it extends the whole length of the big timber-belt and covers a zone from twenty to thirty miles in width. Its grand colonnades run parallel with the general trend of the Sierra. In size it ranks next to the *Sequoia gigantea*, which in all other respects it excels. As a lumber-tree it has no superior. The wood is nearly white, close-grained and solid. No other timber works so easily, nor does any other crack or warp so little, for which good qualities it is in great demand for cabinet-work and interior finish. It is largely used on the Pacific coast, and there is an export demand for it. The sugar made from the sap which exudes from it when cut or otherwise wounded, is utilized for food by the Indians but is not relished by the whites.

Being so valuable for lumber the destruction of the Sugar Pine has been rapid, both the saw-mill man and the shake-maker having until recently been allowed to deplete upon these trees at pleasure. As many of them do not split freely, it was the practice of the early shake-maker to fell one tree after another until he had found one that would rive to suit him. The rejected trunks were left to rot on the ground or to be consumed by the sweeping fires so common in these forests. Under this practice thousands of these trees were destroyed for no other purpose than to prove to the satisfaction of these vandals that they did not split freely. Through the enactment of laws sufficiently stringent to terrorize this class of woodsmen, our Sugar Pines and other valuable trees are now pretty well secured against such wanton and criminal waste.

The white Silver Fir, by reason of its great strength and durability, is much sought after for railway-ties, bridge-building and mine-timbers. Some varieties of the Spruce and Hemlock also make a tough, but rather coarse lumber. The home of these trees, which nearly equal the Yellow Pine, extends along the whole length of the Sierra, reaching laterally from 3,000 to 8,000 feet, the best being found about midway of this belt.

The Incense Cedar (*Libocedrus decurrens*) is another most useful and widely disseminated tree, its habitat reaching from southern Oregon to Mexico, and from 2,000 up to 6,000 feet above the sea-level. In height it ranges from 100 to 150 feet, in diameter from three to six feet. The timber is adapted for a great variety of uses, being light, durable and strong; it is used in railway, ship and boat building. Having a straight grain and riving freely, great quantities of it are split into shakes and pickets, and formerly it was made into clapboards. The bark is thick and tough, and excellent for filling in boggy places in road-building. This Cedar is never found in groves, but is scattered through forests of the Sugar Pine, Yellow Pine, Spruce, Fir and Hemlock, and is often called the White Cedar of California.

Correspondence.

German Forests as I Remember Them.

To the Editor of GARDEN AND FOREST:

Sir,—My memory runs back to the Revolutionary riots which took place in Germany in 1848, when the enraged people resorted to acts of violence in revenge for existing evils. Vibrations from the centres of fermenting dissatisfaction in Paris, Vienna and Berlin had reached provincial cities, and my native place in Mecklenburg was not exempt from this disturbing

visit. Here the rage of the people was directed mainly against the head, or, as he was called, the Senator of the Forest Department, which was a distinct branch in our municipal government. The furious mob, not finding his person, demolished all his belongings, and not a particle of what could be broken in or about his house escaped destruction. Now, why was this punishment inflicted upon him? The charge was that he had appropriated to his own use certain sums received from the sale of timber and wood, and, what was considered a still more serious offence, he had ordered more trees to be cut from the forests than had been allowed by the higher authority, which consisted of a committee of representative citizens appointed for this purpose, whose duty is to designate at certain intervals those trees which, on account of interference with the growth of others or for some other cause, it was thought best to dispose of.

In well-regulated communities the preservation of the forests is a matter of the greatest concern to the inhabitants. With us they brought in certain valuable revenues to the income of the city besides conferring direct benefits to individual citizens. For centuries certain inalienable rights had belonged to the lots on which our houses had been built, under which, according to their valuation, a certain amount of wood could be had for the simple fee of cutting. Persons who did not own real estate, after securing permission which cost nothing, although it was placed upon record, might gather the dry wood which they needed on designated days and in certain places under the supervision of the City Forester or his aids. They could use a wheelbarrow for carrying and a hook to break the dry branches, but no hatchet could be carried. Any one who might be discovered carrying a concealed hatchet had his permission at once revoked. The dry leaves or Pine-needles were also gathered under restriction. The people had learned through centuries of experience, dating back to the times before the Roman occupation, that their forests protected them and helped to provide a means of living for them, and therefore they have always been held in veneration. The result of this long experience is a well-regulated system of tree-culture. It is a luxury to walk through some of these groves. In the oldest sections the giant trees stand in such regular rows as to suggest the thought that they had been originally planted at regular distances.

When wood is sold for building purposes or for use to the different artisans, such as coopers, wagon-makers and joiners, auctions are made, and no one from another place is allowed to bid for it, the privilege belonging exclusively to the residents and citizens. Even the stumps of the trees are dug out and sold for firewood to brick-makers and bakers. In the Pine-woods the long roots are carefully gathered and worked into baskets and similar utensils. Pea-brush, bean-poles, Christmas-trees and decorative greens are cut under supervision, and no slashing and hacking to the right and left is allowed. Now, what is the result of all this care? The people point with pride to their forests, which are wealth to them and a blessing in many educational ways. A fire (*Waldbrand*) is considered a calamity of the direst sort. In the dry season, when leaves have fallen, no smoking is allowed in the woods. Such historical forests as *Wienerwald*, which belongs to Vienna, the *Spreewald*, which belongs to Berlin, and many others are places of renown, but less famous ones scattered throughout the country are cherished and loved by the people beyond description. They feel that they could not exist without them. Besides the value from their wood and protection, in other ways they have great historical interest. Here, we have been taught, are the remains of the graves of the Huns, and here the caves where the Vikings lived and hid their treasures. Here, again, are beautiful openings, where are found such floral treasures as the odorous Violets and Lilies-of-the-valley. In the dark Oak-woods we may startle some deer or wild pigs, and in the Beech-woods are the "horsts" of aromatic berries, and the Woodruff (*Asperula odorata*), which grows in such great clusters that the whole population goes out to gather it for decorating the houses when they plant the May-bush, and all the doorways and stairs are entwined with it at the *Pfingsten* celebration.

We German people miss our forests when coming to this country. We had read the descriptions of the great woods in Fenimore Cooper's Indian tales, but too often we have found nothing but second or third growth trees with tangled underbrush, or burned stumps which told where trees had once stood. It would be well if our people could realize that in the care of their woodlands there lies a refining influence which helps to make a strong home sentiment and nobility of character. We cannot overestimate their economic value, but if every town and village had its forest, in which all the people

felt an affectionate interest, it would strengthen local attachment and add a fresh charm to rural life.

Hartford, Conn.

Wilhelmine Seliger.

Hardy Plants at Short Hills.

To the Editor of GARDEN AND FOREST:

Sir,—It would add very much to the attraction and probably the property value of the average American village to follow the example of Short Hills, New Jersey, and make the vicinity of the station and entrance to the hamlet picturesque. Certainly the requirements are very simple and the expense very slight, the details being only well-kept paths and roads and well-arranged clumps of shrubs, the commonest of these being the best for the purpose. The Spiræas, Forsythias, Japanese Quinces and others at this season make such beautiful masses, that, familiar as they are, we gain pleasure from them at every view, and even those who are whirled through Short Hills on the train must carry away a pleasing impression.

Looking over the hardy-plant nursery of Pitcher & Manda, which occupies the area nearly opposite the station and borders on the main drive, where handsome plantations are maintained, I was reminded of a late editorial of GARDEN AND FOREST calling attention to the fact of our great dependence on bulbous plants for an early display of flowers in this latitude. Of course, few bulbous plants except surplus stock are planted out in a commercial establishment, and the season so far having been abnormally cold herbaceous plants have made little progress. *Adonis vernalis* seemed least affected by chill, and its cheerful flowers and bright foliage made handsome clumps of color. The *Aubrietias* were well forward, *A. Eyrii*, *A. Græca* and *A. purpurea* coming on in the order named. If planted on a rocky these valuable plants would be still earlier. The Dwarf Phloxes, *P. subulata* and *P. amœna*, were well forward, while in a damp spot the double-flowered Marsh Marigold (*Caltha palustris*) was covered with its Buttercup-like flowers. In the frames *Primula Sieboldi* was covered with its graceful clusters of red flowers. There were also stray flowers of *Papaver alpinum* and a few lingering *Hellebores*. Of the large variety of Irises grown only *I. biflora* was showing flowers, in shades of purple. This seems in the way of *I. pumila*, very dwarf, and suitable for dry edgings. In one of the houses was a collection of herbaceous material which had been forced for Easter. The *Pæonies* were well grown and flowered, and seem valuable for gentle forcing, and certainly make bold decorations. Some Foxgloves were about as good as one sees in the open. A large stock of *Azalea Indica* and *A. mollis* is also carried here, and perhaps the most enjoyable part of the establishment at this season is the section containing these beautiful plants—brilliant above most others. It speaks much for the demand for Orchid-flowers that in the houses containing so many thousand plants there is scarcely a flower to be seen, the demand at Easter having taken every available flower on the place, with inquiry for more. Several scores of cases of Orchids were just arriving from collectors in South America, a field which the firm seems to have entered in full force. One might pass a day very pleasantly in wandering through the Palm-house and the numerous side houses, which contain wonderful collections of Bromeliads, Ferns, *Dracænas*, *Anthuriums*, *Crotons*, *Nepenthes*, Palms, etc. In the Fern-house was a grand specimen of the new *Pteris Victoria*, one of the most beautiful introductions of recent years. A curious thing is the Shingle-plant (*Rothos flexuosus*), an Aroid from India, which, growing on a block or wall, creeps up with rooting-stem and throws out leaves alternately to right and left, which partly overlap and lie flat. *Calamus ciliaris* is a rare Palm with fine foliage, which is wonderfully soft and velvety to the touch.

New York.

G.

Sabal Palmetto.

To the Editor of GARDEN AND FOREST:

Sir,—The editorial reference in GARDEN AND FOREST to a letter of Monsieur Naudin on the absence of the Sabal Palmetto in the gardens of southern Europe is of interest in southern California. We also have had no success with this Palm. The only living specimen that I know of is on the Kirmeloa Ranch. This Palmetto is now twelve years old, and yet it is still no tree. The trunk is three feet from the ground to the leaf-stalks. These are long, and look vigorous. The handsome crested curve of the new leaves is very marked. In the same garden there are a number of other Palms, all of which make a fine showing for their age (twelve years). The California Palms, for instance (*Washingtonia filifera*), are in a num-

ber of instances over fifty feet high. The *Chamærops* are between twenty and twenty-five feet, and the Date Palm, which is a slow grower, about the same. This garden is exceptionally well situated for the *Magnolia foetida* (*grandiflora*), for the most vigorous specimens of this beautiful tree in southern California are found there. As this tree is a native of the south, like the Palmetto, it would seem a reasonable presumption that the Palmetto should at least do as well in this garden as anywhere in this section. The *Magnolia*, as a rule, does not make a large tree in southern California. Speaking generally, it is most successful when near the coast. In the interior, where the air is very dry, it is smaller and flowers but little. At Riverside it lives, but amounts to nothing. My idea is that the long dry summers, with cool nights, are unfavorable to both the *Magnolia* and the Palmetto, but less so to the *Magnolia*. The *Magnolia*, while never so large as in the south, is still a favorite ornament in our Coast belt. The Riviera, like southern California, has a comparatively dry climate and cool nights, but it has a lower average winter temperature and naturally an inferior soil. The dryness common to both these climates may be the common cause for the practical failure of the Palmetto.

Lamanda Park, Cal.

Abbot Kinney.

Araucaria excelsa.

To the Editor of GARDEN AND FOREST:

Sir,—May I ask for some information about the beautiful evergreen, *Araucaria*, which we see offered so abundantly in the florists' shops in New York? What is its home and history?

New York.

J. W. K.

[This *Araucaria* is a native of Norfolk Island, and it is frequently known as the Norfolk Island Pine. It is only within three years that the value of young trees for decoration has been appreciated in this country, and last year it was extensively used on or about Christmas. The plants are propagated either from seed or cuttings, both being rather unsatisfactory, as it is difficult to import seeds fresh enough for germination, and, on the other hand, the plants furnish but few cuttings, and these are difficult to root. They must be grown in a cool greenhouse, with an abundance of air and moisture at the roots. Plants raised from cuttings are generally more bushy than those raised from seed, which are spindly and not so well furnished at the base. The great majority of plants used here are imported.—ED.]

Notes.

Mr. Gifford Pinchot, of this city, has been appointed to make the collection of woods from the state of North Carolina for the Columbian Exposition.

Iceland Poppies are opening in the gardens about this city, although the plants were covered with three or four inches of snow a little more than a fortnight ago.

Several forest-fires, of an extent which would excite comment even in this country, have recently occurred in Prussia, devastating large areas near Berlin and near Werdohl, and destroying 1,750 acres of good timber in the vicinity of Niebeck.

The Norway Maples near this city are flowering in unusual abundance this year. Many of the trees are completely covered with clusters of light straw-colored blossoms, and their round heads are conspicuously beautiful now in the sunshine.

In the neighborhood of this city very many *Retinosporas* and other coniferous evergreens have died during the late winter and early spring. In many cases the trees seem to have been injured by high winds and a low temperature which followed close after a very few warm days in early March.

Our native *Carpinus*, or Hornbeam, is one of the most ornamental of our small trees. Its clean Birch-like foliage in the summer, its furrowed bark in the winter, and its trim appearance at all times should encourage its more general use. For a week or so past its catkins have pushed suddenly forward before the leaves so as to cover the tree with a mist of soft green, and present a special feature of the landscape on the borders of swamps and streams.

A correspondent of *The Garden*, London, remarks on the deficiency of color in the English Daffodils this year. In the springs of 1890 and 1891 the crowns of several varieties of the *Incomparabilis* class, such as *Leedsii*, *Cynosure*, *Princess Mary*,

etc., were remarkable for the brightness of their orange tints. This year they have not a single tint of orange. It is suggested that this lack of deep color is due to unusually rapid development. There certainly is a marked variation in the color of the same flower in different seasons, and the causes of this variation suggest an interesting field for investigation.

In order to discover the amount of copper which remained on fruit from vines sprayed with the Bordeaux mixture ten pounds of grapes at the State Experiment Station in Amherst were taken, and the bunches selected were those which had the largest amount of copper mixture adhering to them. In one sample not a trace of copper could be found, and in the other two one-thousandths of one per cent. of oxide of copper was found, an amount so small that one would need to eat from half a ton to a ton of these grapes, stems, skin and all, to obtain any injurious effect.

In Mr. Blomfield's recently published book on *The Formal Garden in England* he quotes from a sixteenth century author, who, in writing upon house-building, declared that the chief prospect of a house ought to be east, and especially north-east, because the "est wynde is temperat, friske and fragrant." Other English authors of the time repeated this assertion, which seems curious enough to those who know what the east wind really is in England; and the fact, says Mr. Blomfield, shows how writers of that period borrowed wholesale from the Italians, "without either acknowledging the source or correcting their statements by local experience."

In a late bulletin from the United States Department of Agriculture on spraying fruits it is estimated that no less than 50,000 fruit-growers in the United States habitually spray their trees and vines against such diseases as the apple scab, the black rot of the grape, etc., while five years ago there was practically nothing known of the subject. In order to get a direct answer to the question whether this practice paid, 250 grape-growers in different parts of the country last year made a series of observations for the purpose of obtaining definite information as to the value in dollars and cents of the spraying treatment for grape diseases. The facts reported by these men show that the actual profit to them over all expenses resulting from the treatment of black rot and downy mildew was \$37,000.

In *Mechans' Monthly* for May there is a note from Professor Maisch on a remedy for poisoning by species of *Rhus* which is worth trying by all who are susceptible to injury from these plants. The remedy is as follows: Saturate a slice of bread with water, cover one surface of the slice with finely scraped washing-soda, and apply this side to the affected part. If the bread becomes dry drop water on the outer side, so as to keep it thoroughly moistened, and remove the poultice in about twenty or thirty minutes. If necessary, it may be applied a second time in the course of a few hours. Another remedy for the same poison is given in the same magazine by Mr. John M. Dunlop, of Milwaukee. The remedy is to paint the parts affected with collodion with a small brush. It shuts out the air and affords instant relief.

The city of Genoa proposes to solemnize the fourth centenary of the discovery of America by international congresses of societies of geography and natural science; and the Italian Botanical Society invites the botanists of all nations to assemble in Genoa on the 4th of September. The Botanical Congress will last until the 11th, and the Italian Botanical Society is arranging for various excursions* on the shores of the Mediterranean and in the Maritime Alps. During the Congress the new Botanical Institute, built and presented to the University of Genoa by Mr. Thomas Hanbury, will be inaugurated, and an exhibition of horticulture and of products exchangeable between America and Italy will be held. Inquiries and communications concerning the Botanical Congress may be addressed to Professor O. Fenzig, of the University of Genoa.

The European horticultural papers have been lamenting the destruction of wild Daffodils in the Basses Pyrenees. Mr. C. Wolley Dod, writing to the *Journal of Horticulture*, states that among indigenous kinds *Narcissus Bulbocodium*, var. *citrinus*, extends over so much territory that, in spite of orders for hundreds of thousands of bulbs, it is in no danger of extermination. The variety *Pallidus præcox*, of *N. Pseudo-narcissus*, has been severely taxed by eradicating collectors for the English market, but for all this it is still abundant in the woods and multiplies so rapidly from seed that it only needs a few years of peace to be as abundant as ever. Besides this it is being largely cultivated, and as the people find how easy it is to raise the bulbs from seed they will hardly go to the trouble

of collecting wild ones from less populous parts of the Basque country.

The Clark Memorial Medal has recently been awarded by the Royal Society of New South Wales to Mr. W. T. Thiselton-Dyer, Director of the Royal Gardens at Kew, for services rendered to the colonies in India through his admirable organization and administration of the Royal Gardens, which have resulted in a system of cohesion and co-operation between that establishment and the botanical gardens of the British Empire. This is the third time the Clark Memorial Medal has been awarded to an official connected with the Royal Gardens, it having been previously bestowed on Sir Joseph Hooker for his work in elucidating the Flora of Australia, and later upon Mr. Bentham for his classical Australian Flora. Those persons who are familiar with Mr. Dyer's remarkable executive capacity and with the state of proficiency to which he has raised the establishment under his charge will hardly agree in his own underestimate of his services as set forth in his letter of acknowledgment, or feel with him that his work has only been the humble one of continuing the traditions which have made Kew as much an imperial as a local institution.

Experiments for protecting the fruit-buds of Peach-trees from injury by cold during the winter have been made for several years at the Massachusetts Agricultural College, and for four years past in the early winter the roots of several of the trees have been loosened on the north and south sides and the trees laid over on the ground. In this way, if the roots are cut off during early summer, the growth will be forced into the roots on the east and west sides, and these will be simply twisted a little in the process of bending over. The trees are bent toward the south to avoid the direct rays of the sun on the trunk and main branches. In the first experiment the buds were injured by heat because the trees were covered too closely; after that they were covered with mats and other light material, and a large percentage of the buds were saved. This spring, while about fifty-two per cent. of the fruit-buds were destroyed on unprotected trees, those which were protected show only ten per cent. destroyed. Many of the trees treated in this way are more than ten years old, and they are easily set up in the spring, grow well and mature a crop. No covering should be put on the ground under the tree, as the moisture seems necessary to keep the buds in good condition, and if the land is in sod the trees should be sprayed with the Bordeaux mixture and with skim-milk and Paris green to protect them from field-mice, which are very fond of them.

In the report of the Botanical Gardens of British Guiana it is said that there is as much difference between a good variety of mango and a bad one as there is between the choicest cultivated apple and the bitterest wild crab. No cultivated fruit rivals the better kinds of mango, while none is probably quite as low as the poorer kinds. By good kinds is meant those without fibre, which are true table fruits, with firm rich flesh, which can be easily cut from the seed. The inferior kinds have stringy flesh, which clings to the seed, and an unpleasant taste like that of turpentine. The range of color in mangos is as wide as the range of quality, some having a combination of tints more beautiful than those of the finest peaches and plums. Others are a beautiful golden yellow, and others still a dull soiled green. The color, however, is no indication of quality, as some of the worst of the stringy mangos are the most gorgeous in color. The mango is a native of India, from whence it has spread quite around the equatorial belt, although it did not reach the West Indies until the second half of the last century. Inferior kinds prevail there, however, because there has been small attempt to import the good ones, and the inferior kinds possess a greater constitutional vigor. Besides this, the peasantry, who are the chief consumers of the fruit, have no preference for the best kinds. The few good varieties which are known in British Guiana are now being propagated by grafting, but they are not at all abundant; indeed, no first-class mango has ever yet appeared in the fruit-stalls of the Georgetown market, nor have the great majority of the inhabitants of the land ever tasted one. There seems to be no reason why, with a proper selection of kinds, the mango should not be included among the ordinary cultivated glass-house fruits of temperate countries. No peaches, apricots, grapes or pineapples in the world rival those grown in glass-houses, and if skill were attained in their cultivation by practice it is probable that finer examples of the fruit of the Mango would be found in English glass-houses than in the tropics. The choicest kinds of Mango-trees might be grown in the great glass buildings at Kew, but there are many dwarf kinds which might be grafted and easily kept to a height of eight or ten feet, and the same diameter of branches.

The American Hawthorns.

OUR American forests are rich in Hawthorns, nearly one-third of the forty species which are now known being found within the territory of the United States. They are scattered from Newfoundland to Vancouver Island and to Florida and Texas, and every state and territory, with the exception of Arizona, contains its representative of the genus. They are more common, however, in the east than in the west, and in the number of species and individuals the south is richer than the north. They abound in the country between the Red River and the Trinity, which must be considered the head-quarters of the genus, as more species occur there than in any other region of similar extent, while individuals of several species grow in greater abundance and luxuriance there than in any other part of the country.

The American Hawthorns have long puzzled students of trees, and botanists have regarded them as difficult subjects. But it is the botanists themselves, rather than the peculiarities of these trees, which have made them hard to understand, and the chief difficulties in elucidating the different species are literary, and not morphological. For many of the species having been early introduced into the gardens of Europe, there developed under cultivation, numerous more or less distinct forms which were described as species, and often as genera, different names being sometimes given to the same cultivated form. This making of species went on for a century in nearly every country of Europe, while in America botanists were hardly less active in burying these unfortunate plants under a load of almost inextricable synonyms. It is, nevertheless, possible to obtain a correct idea of the species if the student will remember that two Hawthorn-plants raised from seeds taken from the same tree may be and probably will look very unlike one another and their parent; that individuals of most of the species vary in the form of the leaves, in the amount and character of the hairs which cover them,

in the presence and absence and in the size and character of the glands which are often found on their leaves and calyx-lobes, in the size and shape of the stipules, which vary on different parts of the same individual, in the number of styles and of the nutlets of the fruit, which is sometimes round and sometimes pear-shaped, and red or yellow in the same species. The student of trees must remember, too, that climate and environment modify individuals, and that when a species has a north and south range of two thousand miles an individual at the north may look very different from one which has grown in the extreme south. If all these facts are remembered, a patient observer able to keep his mind clear of the pitfalls in synonymy dug by Moench and Willdenow, by Aiton and Du Mont de Courset, and by Rœmer, Wenzig and Keleniczko, and with abundant opportunities for studying in their native forests the different species in all parts of the territory which they inhabit may be able at the end of twenty years, perhaps, to recognize the different species and find characters for separating them, although botanists will probably never agree whether certain forms shall be called species or varieties.

The American Hawthorns fall naturally into two groups; the first contains those species which produce large many-flowered compound corymbs, and the second those species with simple few-flowered corymbs. The species of the first of these principal divisions may be divided into three groups; the first with black or blue fruit, the second with large scarlet or yellow fruit, and the third with minute scarlet fruit, while the species of the second of the principal divisions fall naturally into two groups, the first with red or greenish yellow fruit, and the second with large globose red fruit. These divisions being established, there is nothing better than the shape of the leaves, in these plants a variable and therefore unsatisfactory character, by which to distinguish the species.

It is not our purpose to describe here all the American Hawthorns in detail, but rather to call attention to the value of the genus as a good subject for study, promising our readers that they will find in it much interest and excellent opportunities for intellectual development, and to remind cultivators that some of the species are beautiful and desirable garden-plants still too little known or appreciated in their native land.

From a gardener's standpoint the most desirable of our Hawthorns is *Crataegus Crus-galli*, the Cockspur Thorn, which is perhaps better known in cultivation than any of the other species. Its hardiness, the beauty of its lustrous foliage, the lateness of its flowering-time, all recommend it. The head of this tree, which is sometimes round, with pendulous branches, and sometimes flat-topped, with spreading horizontal branches, is always handsome and interesting. The autumn color of the leaves is not surpassed by that of any of the species, and the abundant fruit hangs on the branches without changing color throughout the winter. The Cockspur Thorn is little subject to fungal diseases, which disfigure many Hawthorns, and it is usually long-lived in cultivation. The long thorns which arm its rigid branches make it a good hedge-plant, and early in this century it was much used for this purpose in some of the eastern states. In the form of its leaves the Cockspur Thorn is one of the most variable of our species, and in addition to the varieties which are found growing wild in different parts of the country others have appeared in European gardens, where this species has been cultivated for nearly two centuries, and where it is now more often seen than any other American Hawthorn.

Of the broad-corymbed large-fruited species the White Thorn is, next to the Cockspur, the best garden-plant. This tree has been considered a variety of the Scarlet Thorn and also as a species. Perhaps the latter view is the most sensible, as the two plants differ in size and habit, in the size of their flowers and the time of their appearance, in the size of the fruit and the length of time this remains on the branches, as well as in the pubescence

which covers the under surface of the leaves and the young branchlets. *Cratægus mollis* is the name the White Thorn must bear if it is considered worthy of specific distinction. It is the largest of the Hawthorns of the northern states, and one of the most widely distributed of the American species growing from the shores of Massachusetts Bay to Missouri and through Arkansas to Texas and the mountains of northern Mexico. It is one of the common species in the states west of the Mississippi River, growing to its greatest size in Texas. In cultivation the White Thorn is a beautiful plant, of rapid growth and good habit, conspicuous in winter for the whiteness of its branches and for the number of its large chestnut-brown shining spires. The flowers, with the exception of those of one species of the southern states, are the largest produced by any member of the genus. The leaves are large and of a lively green, and the fruit, which is as large as that of a small crab-apple, is brilliant scarlet with a conspicuous bloom; unfortunately, it falls as soon as it ripens. Some idea of the beauty of this tree when its flowers are open can be obtained from the illustration on page 221 of this issue. It has been made from a photograph of a tree grown in New England, for which we are indebted to Dr. William H. Rollins, of Boston.

The Washington Thorn of the small-fruited species is the best known in gardens; it is the *Cratægus cordata* of botanists, an inhabitant of the southern Appalachian region, and rather a rare plant in its native wilds. It is, however, better known in gardens than any of the other species of the southern states, and its vernacular name is due to the fact that early in the century it was introduced into eastern Pennsylvania as a hedge-plant from the neighborhood of the city of Washington. It is a handsome small tree with an oblong round top, bright triangular leaves brilliant in autumn, and small flowers which open later than those of any of the other species, and bright scarlet fruit the size of peas, which hang on the branches until the leaves appear the following spring. The Washington Thorn is free from serious fungal diseases and is always a satisfactory tree in cultivation. Fifty years ago it was more often planted than it is at present.

An interesting garden-plant, also, is *Cratægus Douglasii*, the only representative of the genus in the coast-region of the north-west and in California. In the warm climate of Washington and Oregon this tree often attains the height of forty feet and forms a trunk a foot and a half in diameter. The leaves are large and lustrous, the flowers are small but very abundant, and the fruit, which is black, falls in early autumn as soon as it ripens. It is one of the few trees of western America which are absolutely hardy and satisfactory on the eastern edge of the continent, where it thrives as far north as Nova Scotia.

Some of the most beautiful of our Hawthorns were once cultivated, but have long been lost from gardens, and a few have never been cultivated at all. *Cratægus flava*, a native of the maritime regions of the south Atlantic and Gulf states, where it grows in the arid sandy soil of the Pine-barrens, was first described a century ago from plants cultivated in England at that time and the source of endless confusion in the literature of the genus, probably long ago disappeared from gardens, although the name still appears in most garden lists. It is a beautiful small tree, with a narrow round-topped head of graceful pendulous branches, large flowers in two or three-flowered corymbs, and pear-shaped greenish yellow fruit. The Parsley Haw, another inhabitant of the southern states, and beautiful from the shape of its finely divided leaves, was once cultivated in English gardens, from which it has, however, long ago disappeared. But the most beautiful of the southern Hawthorns are still unknown in gardens; these are the Pomette Bleue, of the Acadians of Louisiana, and the Summer Haw, of South Carolina and the Gulf states. The first of these, *Cratægus brachyacantha*, although it is one of the largest and most distinct of the whole genus, strangely escaped the knowledge of botanists until very recently, although it was collected long ago without flowers and fruit. It is the

most local of all our species, growing only in the extreme western part of Louisiana, where it borders in broad groves, small low prairies, and in the adjacent portions of Texas. It is perhaps the largest of the genus, sometimes rising to the height of fifty feet, with a tall straight trunk and slender branches, which form a beautiful compact round head. The leaves are not large, but they are bright and shining, and the flowers, which are comparatively small, are produced in many-flowered clusters, which completely cover the branches. The fruit is large and abundant and is bright blue—a color otherwise unknown in the fruit of *Cratægus*. Unfortunately, it falls in early autumn. There is not a more beautiful small tree in the southern states than this, and it is to be hoped that the attempts made a few years ago by the authorities of the Arnold Arboretum to introduce it into the temperate countries of Europe will prove successful. In the Arboretum itself the seedling-plants have not proved hardy.

That no recorded attempt has been made to cultivate *Cratægus æstivalis*, the May Haw, and that no figure of this beautiful plant has ever been published, are remarkable facts, although botanists have known of its existence for more than a century. Unlike our other Hawthorns, it flowers before the leaves appear, in February or March; the flowers are larger than those of any other species, and the fruit is larger and of better flavor and quality than that produced by any other *Cratægus*. It is as large as a medium-sized crab-apple, bright red with pale spots, and ripens in May. Pomologists might well devote some attention to this tree, for excellent jellies can be made from the fruit, which is gathered in large quantities for this purpose and is sometimes sold in the markets of the towns of western Louisiana, where this tree is most abundant and best known.

We have only briefly mentioned a few of the species which seem best deserving the attention of gardeners, although among the others are several handsome plants which are hardly known to the cultivators of this generation.

The Love of Nature.—III.

WE have endeavored to show that the true love of nature means a broad receptiveness of eye and mind which does not need striking scenery to delight it, but finds beauty and interest in the quietest, simplest scenes, and which does not need constant change to stimulate it, but loves familiar things better and better as they grow more and more familiar. Every one realizes that more kinds of art appeal to its real lover than to the ordinary observer, and that striking spectacular kinds are not exalted by him above all others. All the greatest artists in the world did not paint Sistine ceilings or Venetian triumphs, and some of the world's most famous masterpieces measure only a couple of spans and do not show a single vivid note of color.

So it is with nature and its masterpieces. The finest compositions wrought with mountain-peaks and deep ravines are not really more beautiful or wonderful than those which can be wrought with a gray boulder, a Pine-tree and a carpet of Moss and Ferns; the most splendid panoramic background is not more enchanting than may be a foreground of flowery meadow with a middle distance of woodland, and no background at all except the luminous sky.

Some persons, of course, are born with a true and deep love for nature. But even in them, we think, this love does not develop very early in life. In the majority of cases it seems to have been gradually developed rather than spontaneously felt. And while no one not born with a poet's soul can ever learn to feel Nature's beauties as a Corot or a Wordsworth did, any one can learn to see these beauties, unless his mind is hopelessly sluggish and prosaic.

How, then, can such knowledge be acquired? One way is the landscape-painter's way. The practice of painting, even in the most untrained and amateurish fashion, is, if

sincerely pursued, an excellent help toward the development of a love for nature. If an intelligent young girl would spend an hour a day during a single summer faithfully trying to set down in paint what she sees in nature—now a flower or a branch, now a bit of sunset-sky, a corner of a hedge-row or a little stretch of river-bank—she would find at the end of the season that she had gained new eyes. She would see a thousand things she had never seen before—find beauty in many that before had seemed ugly, and realize the difference between merely “liking” nature and truly appreciating it. It would not matter if all her studies were failures and were torn up in disgust as fast as they were finished. She would have attained a great end, achieved a real success; for she would have enlarged her own powers of enjoyment in a way that would sweeten and dignify all the rest of her life. A vast amount of amateur sketching is done in this country every summer, but we fear it is not often done in the spirit and manner we have indicated. The aim is to produce pretty pictures, not to cultivate the painter’s own intelligence. And while the aim generally remains unattained, intelligence is scarcely increased; for as the excellence of the sketch has been the ruling motive, a subject has most often been chosen because it was easy to do, not because it was exceptionally interesting in itself.

Of course, a thorough scientific acquaintance with natural things need not precede a deep and full enjoyment of them. Indeed, great devotion to scientific study occasionally seems, as in the self-confessed case of Darwin, to kill the æsthetic sense. But this is not because science and a love of beauty are necessarily at variance. It is simply because the powers of the human mind are limited, and intense absorption in one aspect of nature may leave no room in life for constant consideration of another side.

To know the names of plants is often thought by the uninstructed to be the aim and end of botanical study. But a mere acquaintance with these names is not knowledge in the true sense. It is only a necessary step in the gathering of knowledge. Names of plants are important just as names of persons are. We must discover the name of a stranger if we are to identify him, to understand his place in society and the world at large, to remember his individuality, and gain more information about him by speaking of him to others. And so with the name of a plant.

In studying botany we learn first such facts as we naturally know about human beings. We learn what they are, how they live and grow, what is meant by their nearer or more distant degrees of relationship, how and why they are grouped in what may be called families, clans, communities and nations. And as those who have studied them most profoundly have discovered that their relationships depend upon their structure, we must study on these lines to gain any knowledge that is satisfying.

Surprising are the minute and subtle beauties that will reveal themselves when a plant is studied as well as merely contemplated; and surprising are the interesting facts that will reveal themselves when its special place in the plant-world and its relationship to other plants are understood. This enlargement of knowledge deepens interest, and, if æsthetic susceptibility exists at all, greatly widens the scope of enjoyment. To a person who knows nothing of botany, the trees and flowers which he calls familiar are like attractive faces which we meet day after day in the street but cannot call by name and have not the privilege of speaking to. To one who has some knowledge of it, familiar plants are like friends about whom everything is known, and new ones are like attractive strangers with whom we can instantly make acquaintance. The same distinction is true in regard to the larger and more permanent features of a landscape. These features present themselves as one picture to those who know nothing of geological science and quite another and a much more profoundly interesting one to those who have some true idea of the constitution and history of the solid crust of the earth.

The true lover of nature, said William Blake, can “see a world in a grain of sand and heaven in a wild flower.” But such a power of seeing is not given to many persons at their birth. Eyes are of very little use to most of us unless we have learned how to use them. And the best way to learn how to use our eyes is not to cast them about idly, even though we may take pleasure in so doing, but to discover what there is to be seen in the world and then to try to perceive it all. The wise man not only knows nature better than the ignorant man; he also sees it very differently; and in this difference lies a vast unlikeness in the amount of pleasure that is gathered by their eyes. But to be wise in this sense one need not be learned in the scientific sense. One need only devote a fraction of his time to a careful study of the natural sciences so as to have a rudimentary knowledge as a solid basis for the superstructure which imagination can be trusted to rear. Any person who possesses the rudiments of a love for nature, whose soul is naturally open to the influences of beauty, will surely go on, by means of personal observation, to a stage of development where his appreciation of and affection for natural objects will grow with his ever-increasing knowledge of the laws and processes which are the subjects of scientific study.

THE forests of India offer a most instructive object-lesson for Americans. The waste of valuable wood by the axe and by fire was almost as reckless in that country as in our own until the Government began to take measures to protect it. The first efforts did not strike at the root of the trouble, and therefore much time was wasted until Doctor (now Sir Dietrich) Brandis began working in the right direction. The central idea of Sir Dietrich was that the state should manage the forests for the distinct purpose of securing a revenue, and under his administration marked progress was made at once. Our own forests should be preserved for other reasons than merely to insure a lasting timber-supply; but, with the example of India before us, where the forests now yield a revenue of two million of dollars a year, there seems no reason why our own public forests, if properly managed by the Government, should not pay for their protection. It will be a great gain for this country when we learn that forest-lands can be wisely cut over without destroying the forests.

These reflections are suggested by the annual report of the Forest Department of the Madras Presidency for the official year, 1890-91, which contains the usual record of work accomplished in the year. It appears that the area of reserved forest increased 360 square miles during the year, and that the total area of reserved forests and reserved lands in the southern circle amounted to 8,701 square miles. Some of the difficulties which the forest-administration in India has to encounter appear in the fact that it had to bring 3,990 cases of prosecution for trespass and injury to the forest. Most of these were offences for unauthorized felling of wood and for grazing without permission. Conviction was secured in eighty per cent. of the cases prosecuted. Fires, as is always the case in Indian forests, did much damage, one area of 2,700 acres alone having been burnt over. The report states that before the inauguration of the forest-system “it is not too much to assert that the more valuable timbers—that is, the Teak and Rosewood—were being exterminated in all the accessible forest-areas in the southern districts—first, for want of protection, and later on by heavy fellings of all mature trees, without any proper system of care for reproduction and insufficient protection”—a state of affairs which may be seen in every park of North America. The revenue derived from the working of the forests in Madras during the year was the highest on record, and the authorities believe that it will increase largely in the future as the system becomes more fully developed and fairly established.

In the May number of the *American Journal of Science and Arts* Professor William H. Brewer prints an interesting

and sympathetic obituary notice of our late associate, Mr. Sereno Watson, in which, discussing the causes which influenced his career and enabled him to obtain a distinguished position among men of science, Professor Brewer remarks that, "had he died twenty years after graduation, the world would have known little of him, and his classmates would have considered his life a failure. That long period was, however, years of diversified preparation which fitted him to bring to his chosen work most thoroughly trained powers, and gave him a wide range of knowledge drawn from the study of several sciences, and a personal knowledge of the aspects of the flora of many widely separated parts of the country. The reserve which characterized him in college, and which lasted through life, left him all the more free to prosecute his chosen work without the distractions of society. But his reticence was not that of the misanthrope; he endeared himself to all who were brought in close relations with him. This was strikingly shown in the trials and hardships of camp life, as among the inner circles of his friends in the university and in the few families which had the privilege of his acquaintance."

Spring in the New Jersey Pines.

ALMOST all of the flowers in the Pines are tardy in their appearance this spring. A few, however, greeted us as usual despite the cold. Our charming Pyxie (*Pyxidantha barbulata*) was full of bloom early in April, and the Trailing Arbutus was redolent with sweetness at the same time. Although these shy woodland treasures are now past their prime, yet we still find lingering sprays of both, which have been kept in check by the cold.

The Wind Anemone is in flower in damp places. Its pretty blossoms are pinkish purple on the outside, while the inner surface is pure white. In grassy places we find violets innumerable, from deepest blue down to light shades of purple and lilac. All these are varieties of *Viola cucullata*, and they have leaves as varied in form as the flowers are in color. Some have palmate leaves, others broad heart-shaped ones, while many are nearly round. The Arrow-leaved Violet (*V. sagittata*) is also abundant and almost as variable in the form of its leaves as *V. cucullata*, but the color of the flower is a more constant blue in this species. The little white Violets, *V. lanceolata* and *V. blanda*, are here too, giving us a sweet perfume with their delicate beauty. The Bird's-foot Violet (*V. pedata*) is just coming into bloom. This is our finest species. The handsome flowers are large and brilliant, in varying shades of blue and purple, down to the purest white, while some have the petals striped and blotched. The leaves are pretty too, but not quite as handsome as those of the Larkspur-leaved Violet (*V. delphinifolia*) whose habitat is on the western prairies. It is established in my wild garden, however, and flourishes as well as any of its kindred. The leaves are longer and larger and more finely dissected than those of *V. pedata*, and the clumps of foliage are pretty all summer. The flowers are deep blue and do not vary in color, and are small compared with the Bird's-foot Violet. Of the leafy stemmed violets, I have found only *V. canina* in the Pines, unless we can establish the fact that *V. tricolor* is indigenous. This species I have seen in old neglected fields, but never where the ground had not at some time been cultivated.

The little heath-like *Hudsonia tomentosa* is beginning to light up the gray sandy places with its bright yellow flowers. Before it blossoms, its downy, sharp-pointed, grayish leaves so blend with the sand that it is scarcely discernible a few feet distant, but during May it makes the waste places gay with color. *Helonias bullata* is very late coming into flower this spring. For twenty years or more I have not failed to find it in blossom in April, and now it is only in bud with the flower-scape only five or six inches in height. But the Golden-club (*Orontium aquaticum*) was not to be kept back by the cold. It was in flower by the middle of April, but the leaves were seared by frost while the flowers were not hurt at all. The leaves of this plant when perfect are very handsome; they are large and present a deep green, rich, velvety upper surface that sheds water, while the under surface is very smooth and of a light color, and always wet or moist. *Arnica nudicaulis* is in flower, each stalk surmounted with several heads of deep orange flowers—very pretty and attractive; and the modest little plantain-leaved Everlasting was in bloom early in April, and still continues to flower in dense patches along the road-

sides and in the barrens in company with its more showy neighbor the Arnica.

The false Dandelion (*Pyrrhopappus Carolinianus*) is growing here on the roadsides and in the fields. I noticed it for the first time three or four years ago. It is supposed to be a more southern plant, but it seems to be perfectly at home here. Its bright yellow flowers are quite pretty on a branching stem—solitary on each branch. The stem is a foot or more in height. *Potentilla Canadensis* was blooming in April, and its variety, *simplex*, is just coming into flower. Are not these two plants dissimilar enough to be classed as distinct species? *P. Canadensis* always creeps, while its so-called variety is erect and stout, with more vivid green leaves than those of the type. The flowers in both are similar, and this is the only justification for considering one a variety of the other.

Only a few flowering shrubs are in bloom as yet. *Cassandra calyculata* has been very full of blossoms, but is on the wane now. *Leucothoe racemosa* is in flower, and *Amelanchier Canadensis*, with its many varieties, is everywhere in the damp barrens. Some have pure white flowers, and others pink and rosy like Apple-blossoms. The red fruit of the swamp Maple is strung thickly along the branchlets, and is very showy and handsome, and the yellow flowers of the Sassafras make a lovely combination of color. The red berries of last year still cling to the Hollies and to *Ilex verticillata*, while beneath our feet are the spicy Wintergreen berries and the paler red of the Partridge berries. The shining black fruit of the Inkberry (*Ilex glabra*) is abundant, and also clusters of the purplish black fruit of *Smilax*. *Negundo*, with its delicate drooping clusters of flowers, is handsome now, and blossoms of Sweet-gum still linger as well as those of the Tupelo.

Vineland, N. J.

Mary Treat.

Plant Notes.

Some Recent Portraits.

IN the April number of the *Botanical Magazine* are figures of *Lilium primulinum* (t. 7227), a plant recently imported by Messrs. Hugh Low & Co. from the Shan states in Upper Burma. Its nearest allies are *L. Nepalense* and *L. Neilgherrense*. It produces a stiff erect glabrous stem three or four feet tall, with scattered lanceolate, sessile glossy bright green leaves three or four inches long, and about three flowers arranged in a corymb or umbel on long-nodding pedicels, each with a large lanceolate leaf at the middle. The perianth is open, funnel-shaped, pale yellow without spots, and tinted on the outer surface with green while young, and is five or six inches long; *Habenaria longecalcarata* (t. 7226), one of the long-spurred species of India, characterized by the large flowers and the great length of its spurs; *Cirrhopetalum ornatissimum* (t. 7229), a native of Assam and the eastern Himalayas, a plant which much resembles *C. Collettii*, previously figured in the magazine (t. 7198), although differing from that species in the form of the pseudo-bulbs and in the erect scape springing from the side of the pseudo-bulb, and not pendulous and developed from the young growths before the new pseudo-bulbs are formed, as is the case with the second species. It is rather as botanical curiosities than as ornaments of the garden that these plants will be cultivated. *Streptocarpus Galpini* (t. 7230), already described in our columns; *Beaufortia sparsa* (t. 7231), a brilliantly flowered shrub with a curious inflorescence, which presents the appearance of a spike the axis of which is produced above into leafy branches, but which in reality is the result of a consecutive series of closely contiguous leaves being reduced to bracts and producing each in its axil a flower, the whole being hidden by the bundles of pendulous stamens. In *B. sparsa* there are about five of these bundles in each flower, each bundle consisting of a thread about an inch long bearing about eight long-stalked diverging filaments, of which two are opposite and placed considerably below the five that terminate the thread. *B. sparsa* was discovered late in the last century by Archibald Menzies, the surgeon and naturalist of Vancouver in his voyage of discovery, on the shores of King George's Sound, in south-western Australia, where the town of Albany now stands, a locality well known for its rare and beautiful

Fig. 40.—The White Thorn (*Crataegus mollis*) in New England.—See page 217.

plants, and known as the only habitat of the Australian insectivorous plant, *Cephalotus follicularis*. It has been known in cultivation for half a century, although, like many other plants of its class, it is now much less frequently seen in gardens than it deserves.

Foreign Correspondence.

London Letter.

NEW CATTLEYAS.—On March 4th last Messrs. F. Sander & Co. offered for sale a *Cattleya* which they had named *C. Victoria Regina*, and described in the sale catalogue as a new species, with flowers five inches across and as many as eight or nine on each spike. Their color was said to be glossy deep rosy red, with blotches of crimson and purple, paler on the margins, which were wavy; the lip crimson, with a white tube. The pseudo-bulbs, foliage and general appearance of the plants in the sale-rooms strongly suggested *C. amethystoglossa*, now called a variety of *C. guttata*, but Messrs. Sander & Co. say there are good differences between their new one and any of the known forms of *C. guttata*, and, also, that the plant is found wild in a locality far removed from that where *C. amethystoglossa* comes from. The plants have not yet flowered, but, judging by a specimen in the Kew collection, they ought to prove easy to manage. A considerable number of plants were sold at the sale. This week the Messrs. Linden, of Brussels, advertise the sale of another new *Cattleya* for April 29th, which they have called *C. Alexandræ*. A description of the plant by Mr. Rolfe is published in this week's *Gardeners' Chronicle*, from which it would seem that this also is a near ally of *C. amethystoglossa*, pseudo-bulbs and leaves resembling that plant very closely. Its most remarkable character, however, is the length of the peduncle or flower-stalk, which is from fifteen to eighteen inches long and bears from six to ten flowers. The color of the flowers is described as being similar to those of *Lælia grandis tenebrosa*. I shall not be surprised if, when this and Messrs. Sander & Co.'s plant flower, they prove to be one and the same.

CYPRIPEDIUM EXUL.—This plant was described in the *Gardeners' Chronicle* last year by Mr. H. Ridley, Director of the Botanical Department in the Straits Settlements, from specimens collected in Assam. It was, he said, a very distinct variety, both in form and coloring, of *C. insigne*. Plants of it were sent to England, and one of them was exhibited in flower last Tuesday by Mr. R. I. Measures. This differed so markedly from what we know as *C. insigne* that it was considered expedient to elevate the plant to the rank of a species, which has been accordingly done by Mr. O'Brien, whose description, with a drawing of the flower, has been published in the last *Gardeners' Chronicle*. Mr. O'Brien points out the resemblance in the leaves and form of the flowers of *C. Exul* to *C. Druryi*, which, however, has yellow flowers, while those of *C. Exul* are colored like *C. insigne*, var. *Maulei*. The plant was imported in large quantities into England in 1891 and sold as the Siam form of *C. insigne*. It is distinct, but not attractive in color, and is not likely to become a favorite except, perhaps, with those who have the *Cypripedium* mania.

ODONTOGLOSSUM WENDLANDIANUM.—This is a new Sanderian introduction, of which a plant in flower received a first-class certificate from the Royal Horticultural Society on Tuesday last. It is in the way of *O. niveum* or *O. blandum*, some suggesting that it is a cross between the latter and *O. Andersonianum*. The sepals and petals are narrow, elegant, creamy white with chestnut blotches, the lip white spotted with rose-purple. It is a pretty little Orchid, quite equal to the best forms of *O. blandum*.

CATTLEYA BURBERRYANA, a cross between *C. intricata* and *C. superba*, received an award of merit, as also did a hybrid *Cattleya* from Messrs. J. Veitch & Sons, named *C. Philo*, a hybrid between *C. iricolor* and *C. Mossiæ*.

RHODODENDRON RACEMOSUM.—An exhibit of more than ordinary interest at the last meeting of the Royal Horticultural Society was a basket filled with plants in flower of a charming little *Rhododendron* with the name at the head of this paragraph. The plants did not exceed six inches in height, and they were not unlike ordinary Box in habit and foliage. The flowers, which were arranged in loose heads four inches across, were three-fourths of an inch across, shallowly campanulate, colored pale rose, with a deeper margin. They were slightly fragrant and altogether delightful little bouquets. The plants were from the Coombe Wood nurseries of Messrs. J. Veitch & Sons, where they had been growing in the open ground all winter, and had been lifted only a few days before they were shown in flower. From this it would appear that this tiny *Rhododendron* is hardy near London, and a most promising little plant for the garden. The name, however, may possibly be wrong. *R. racemosum* was described by Franchet from specimens collected by Delavay in Yun-nan. There is a type specimen of it in the Kew herbarium, and this differs in several important points from the plant called *R. racemosum* by Veitch, the scales on the stem being different, the flowers smaller, the pedicels shorter and the leaves larger and thicker than those of the plants shown in flower. Furthermore, there are specimens at Kew of *R. parvifolium* which agree very well with Messrs. Veitch's plant, and which are of Chinese origin. But we have also in cultivation a plant called *R. parvifolium* which is poor in comparison with Messrs. Veitch's new introduction; in fact, is scarcely worth a place in the garden. *R. parvifolium* is, however, found in Siberia as well as in China, and it may vary considerably, as do many of the *Rhododendrons*. We have at Kew a plant called *R. racemosum* which was certainly raised from seeds collected by Delavay, and this looks like that of Messrs. Veitch. But, whatever its name may be, Messrs. Veitch & Sons are to be congratulated on having a new *Rhododendron* distinct in character, pretty, and full of promise as a hardy plant. This is the second to flower in England of the new Chinese *Rhododendrons*. Of course, it obtained a first-class certificate.

HYACINTHS.—The monopoly of the bulb trade by the Dutch is probably due to cheap labor as well as to the natural advantages which the peculiar character of the soil and lowness of the country afford. Custom, too, has, no doubt, much to do with it. We buy bulbs from Holland for the same reason as we buy knives from Sheffield. But first-rate bulbs, equal to the best Dutch, can be grown in England. We know this with respect to Daffodils and Tulips, and we may now add Hyacinths. For the last five years Kew has made the experiment of raising Hyacinths from bulbils, growing them on in nursery-beds, lifting them and storing them in a dry shed for the winter and removing the flower-spikes as soon as they open until the bulbs are full size, when they are planted in the flower-beds for spring effect. At the present time the whole of the large geometrical flower-garden in front of the great Palm-house is filled with about 10,000 Hyacinths, all in full blow, every one of which has been raised at Kew in from three to five years from bulbils. Samples of the spikes were exhibited before the Royal Horticultural Society last Tuesday, and they were generally admitted to be equal to those of Dutch origin. Of course, I do not mean by this to suggest anything beyond the fact that many people might find pleasure and satisfaction in growing for themselves bulbs which are now purchased annually and thrown away after they have flowered. From the commercial standpoint I question if it would ever be possible to produce in England bulbs equal to those grown in Holland, and at the same time as cheap.

AUSTRALIAN PLANTS.—The greenhouses at Kew owe not a little of their charm at this time of year (April) to the various Australian hard-wooded plants, so called, which have received special attention at Kew during the last few years. The most noteworthy are the Acacias, to which I

have previously referred, the Chorizemas, Pimelias, especially *P. Nieppergiana* and *P. spectabilis*, the latter a charming pot-plant, with many branches, every one terminated by a head of creamy white flowers as large as a crown-piece. *Pultenœa flexilis* is a bush, eight feet high and as many across, with branches most elegant and graceful, the whole so thickly studded with bright yellow pea-like flowers as to suggest a cloud. This is planted out in a peat-bed, and I know of no shrub, indoors or out, that surpasses it. Close to it is a large bush of the allied *Eutaxia myrtifolia* and another of *Aotus gracillima*, whose long wand-like branches, clothed with yellow and brown flowers, are a delightful feature. The white orange-like flowers of the various *Eriostemons*, the elegant, brightly colored *Epacris*, and the white star-like flowers of the graceful *Leptospermums*, with the rosy bells of *Baucria rubioides*, are all such as arrest attention and win general admiration. The brilliant *Boronia heterophylla*, grandest of all *Boronias*, is now worth going a long way to see. These, and many others which one might mention, are first-rate garden-plants when well grown, far more attractive in every way than hosts of the things which are in general favor.

Peat, plenty of sunshine and air, with the exclusion of cold and damp in winter, are the principal factors in the production of good specimens of hard-wooded plants for the greenhouse, such as those mentioned above.

Cultural Department.

The Cultivation of Ginseng.

THERE was a touch of pathos in a remark I heard from a farmer's wife while rambling over the hills of Cortland County, New York, in quest of Ginseng. "It is a shame," said she, "that Ginseng is so hunted and stolen from our forests that we can hardly find a root for our own use." From Minnesota to Carolina the gathering has been carried on until in the places where this beautiful plant was once so abundant that one could hardly step without treading on it, only single roots can now be found. It is only a question of time when Ginseng, at the present rate of destruction, will be utterly exterminated from our forests. Last year more of the root was exported to China from this country by 80,000 pounds than was ever sent before in any single year, and notwithstanding the growing scarcity there are ten persons hunting for the roots now where there was one ten years ago. From early spring to late fall the Ginseng-hunter toils with his bag and spud through tangles of brush and brier, his day's labor often rewarded with only a few ounces of roots, while a more fortunate chance may give him as many pounds some other day. The hunt has been greatly stimulated by recent high prices, and there is, too, a fascination about the quest which is only known to those who engage in it.

Ginseng is one of the most beautiful plants found in our forest. Its form is symmetrical, its foliage is delicate and its seed-head is beautiful. It is often described as a fifteen-leaved plant, but it has really from three to twenty-five leaves, according to its age and vigor. In central and northern New York it comes out of the ground about the first of May. The leaves attain their full size in June. The blossoms appear about the first of July, and are very small and delicate, and under a magnifying-glass beautiful. The berries develop rapidly, and are light green until the 20th of August, when they commence to color; in September they are bright scarlet and make a very showy appearance. A large, vigorous, twenty-leaved plant may have as many as thirty or forty berries in a round compact ball on a slender stem from four to six inches in length, each berry containing from one to three hard rough seeds. The berries are round and elongated or triangular in shape, according to the number of seeds, and they are often as large as a small bean, and are meaty and pleasant to the taste. They fall to the ground soon after ripening and are covered by the falling leaves. But since one covering of leaves would not suffice to protect the delicate root as it first pushes from the seed, nature provides that the germ in the little seed shall patiently rest until another year has spread another covering of leaves over it. Then, after the snows of a second winter have rested upon the seeds and firmly imbedded them in their position, they

awake from their sleep of eighteen months and send up a small plantlet about two inches high, with three leaves, and a root not larger the first season than a grain of wheat.

The plant grows slowly and attains a great age. Roots, thirty or even fifty years old, often weigh less than one ounce, and again they have been found weighing three and even six or eight ounces, though not nearly as old. How do we know the age? By the notches on the neck of the root. The plant keeps its own record, each year's growth adding to the length of the neck and leaving a notch where the stalk falls off. As the roots increase in age they assume strange and fantastic forms, so that it requires but little imagination to see the form of the human body in many of them.

Ginseng also grows in China. In his *Middle Kingdom* Williams says, "It is found wild in the forests of Manchuria, where it is collected by detachments of soldiers detailed for the purpose. These regions are regarded as imperial preserves, and the medicine is held as a Government monopoly. The importation of the American root does not interfere elsewhere with the imperial sales, as the Chinese are fully convinced that their plants are superior." The root has been exported to China from this country for more than a hundred years. At first it was bought of the Indians at \$2.00 a bushel for green roots. Within the last few years local dealers have paid as high as \$1.15 for a pound of green roots, while the dry root has sold as high as \$4.25 in New York. But for the foreign demand it would not be worth more than five cents a pound here, and our forests would soon be filled with the plant. It is sometimes sold for its weight in gold in China, and at other times for its weight in silver, according to its supply and demand. A single root having the form of the human body may bring from \$2.00 to \$4.00. In the *Oil, Paint and Drug Reporter* for May, 1889, it is said: "An example of the cost of this medicinal root is afforded by a recent *Pekin Gazette*, which contains a report from the Military Governor of Kirin, stating that he has forwarded by special messenger for the Emperor's use eight large and sixteen small roots weighing together nine and four-tenths ounces. The total cost is given as 1,560 taels, or about £400, being at the rate of £45 an ounce." The Chinese do not base their estimate of its value upon chemical analysis of the root, but they reason that a root which attains such extreme age and so resembles the human form must possess supernatural power, and that therefore it is capable of imparting its virtue to the human body; hence if they eat such roots they will ward off disease and prolong their lives to extreme old age.

It is the general opinion in this country that the plant cannot be successfully cultivated. In 1891, while attending the State Fair with an exhibit of Ginseng, I was told by more than a hundred people that they had tried to cultivate the plant by setting roots and sowing the seed, but that it never grew. And this was my own experience at first. My first sowing of seed did not produce a plant. Two hundred roots which I put into the ground in 1886 made little growth the first year, and the outlook was so unfavorable that I abandoned the business. In 1887 I put in some roots and sowed some seeds, and the next year my plants made a better showing. I then commenced to study the habits and characteristics of the plant, and, with the experience gained, my success has been complete. I had thousands of fine plants growing on my ground in 1891. Many roots can be grown in a small space, and although the growth on each one during the season is small, yet the aggregate is considerable. The plant will grow much more rapidly under cultivation than it will wild, and it therefore seems destined to become an important agricultural product. The seed alone will pay for the expense of cultivation, and there will soon be a demand for all there can be produced. The Legislature of Ontario, by its recent action in passing the law to prohibit the digging of roots between the 1st of January and the 1st of September, has taken a step in the right direction, and it would be well if our state legislatures would pass similar acts for the protection of the wild plants in this country.

There is a general impression that our Ginseng may be grown in the forest, but that it cannot be successfully cultivated in the open garden or field. Of course the forest is the natural home, and when it is once established in the woods it will require but little care or attention. The only danger would be in protecting the crop. Ginseng, along with other medicinal roots growing wild, is by common consent regarded as free plunder, and the average Ginseng-hunter would hardly have so fine a sense of honor as to discriminate between the wild and cultivated plants. In the forest any light soil will answer, so long as it is not wet or swampy. All that is necessary is to place the seeds or roots in the ground, and nature will do the rest if time is given. My own operations have

been in the open garden. Small roots may be set three inches each way, and seed may be started much closer and transplanted in two or three years. Experience will show the best method of shading. I have found that shade of some kind is essential. All that is needed, then, is weeding and careful cultivation. From an area measuring forty-feet in length by three feet in width I lately took 570 roots, weighing 18 lbs. 14 oz.; 343 of these were small, and weighed together 5 lbs. 7 oz., which I reset. The remainder weighed, when dried for market, 4 lbs. 12 oz., for which I received \$16.83, besides fifteen ounces of seed, for which I have a ready sale at \$1.00 an ounce. Of course there is much to be learned as to the best methods of planting and cultivation, but the cultivated root is firmer and shrinks less in drying than the wild article. In my opinion the growing of the plant can be made profitable, even if the root does not bring more than \$2.00 a pound.

Summit Station, N. Y.

G. Stanton.

flicted in a similar manner and recently studied. To cure such leaves seems out of the question, and what to do as a preventive is not easy to suggest. Some one with a fondness for life-histories of nematodes might well devote much time to the answering of many practical questions concerning these foliar eel-worms.

Rutgers College.

Byron D. Halsted.

Euphorbia Jacquinæflora.

THIS plant, a very old inhabitant of our greenhouses, is more correctly known as *E. fulgens*, but to the present generation of gardeners it will be the more familiar by the old name. Like *E. pulcherrima*, which is also better known as *Poinsettia*, it is a native of Mexico, and both are naturalized in Florida in the Orange belt, and make a gorgeous display at Christmas-time out-of-doors. It is well known that it is the colored bracts of the *Poinsettia* which make it so conspicuous, but in its near relative it is the flowers themselves that are ornamental. These are produced in short axillary racemes at the extremities of the shoots, and the quantity of flowers depends entirely on the strength of the shoots. For this reason we prefer to grow the plants on quickly to a single stem, not pinching the tops out at all, as one good stout spray twelve to eighteen inches in length studded with bright orange-scarlet flowers is much preferable for cutting purposes to smaller sprays, even if more numerous. Under pot-culture, *E. Jacquinæflora* has a rather bad reputation, it being somewhat liable to die off just above the soil. Too much or too little water will produce this result, but we find that when planted out in benches in an ordinary Rose-house temperature a vigorous healthy growth can be obtained, with very little danger from the trouble referred to, with an abundance of bloom at a season when cut flowers are in great demand. Another feature of this plant is, that the flowers will be produced on the plants in succession for more than two months, so that there is no trouble in saving them for any special purpose or occasion. It is well known that *Poinsettias* wilt badly when cut and put in water, but if cut and the whole stems submerged in water, and the bracts allowed to float for about twenty-four hours, this difficulty may be entirely overcome, and the same treatment can be given to the *Euphorbia*. This was discovered quite by accident, when a lot of wilted branches of *Poinsettias* were placed in a bath-tub to preserve the bracts; the stems are capable of absorbing a quantity of water and storing it for use. We find *Euphorbias* root easily when the young shoots are taken off close to the old stems, or "with a heel," as it is termed by propagators. These are potted up when rooted, and grown on into four-inch pots, and from these transferred to their permanent places in benches wherever there is root-room. The growth made is somewhat slender, and does not shade or otherwise interfere with other occupants of the house or benches, and the temperature and soil of a Rose-house suit them admirably.

South Lancaster, Mass.

Fig. 41.—Leaf attacked by Nematodes.

Foliar Nematodes.

THE most striking instance of eel-worms destroying the leaves of plants which has come to my notice was seen on specimens of *Ficus comosa*. When first observed nearly all the leaves were badly blotched, and several of the lower ones had fallen away. Upon the upper side the leaves have a bronzed appearance, while the lower side is brown and somewhat rusty in color. As has been heretofore observed in *Coleus* and *Salvia*, the nematodes do not destroy the life of the leaf-pulp uniformly, but, instead, ruin it in spots that are decidedly angular in outline, the boundaries corresponding to the veins of the leaf. In the worst cases the whole leaf may become brown and dead. The engraving illustrates the appearance of a leaf that is attacked to only a moderate degree, and was selected for the photographs on this account. It will be noticed that the diseased area is the central portion of the leaf, and its position leads one to wonder if the worms may not have come up from the soil or roots through the stem and leaf-stalk. This seems to be the case with young Ferns af-

Notes on Species of Tulips.

DURING the last twenty years many species of Tulips have been re-introduced into cultivation, principally through the exertions of Dr. Regel, of St. Petersburg; they are interesting, and vary in the form and color of the flowers, and some are quite new in gardens. *Tulipa Batalini* produces exquisitely shaped flowers, straw-colored in one form and deep scarlet in another; the flowers are of medium size, but beautifully proportioned. *T. Korolkowi marginata* is an early-flowering species, with small but well-shaped, brilliantly colored flowers, the segments deep scarlet and margined by a broad band of brilliant yellow. *T. Kaufmani* is one of the earliest-blooming species, or perhaps the earliest. There are two forms: one with flowers straw-colored inside and rose or purple outside, and the other with flowers golden yellow, blotched with bright scarlet. Bright red outside and straw-colored within are the flowers of *T. Leichtlini*, introduced by myself from Cashmere. This is a rather dwarf, small-

flowered species, but is attractive. *T. Greigii*, a species with large, bold, brilliantly colored flowers, is already well known. The largest-flowering Tulip I know is *T. oculis solis*, var. *mervensis*, a peculiarly stately plant, with scarlet flowers blotched with black. *T. Turkistanica* is a curiosity, producing sometimes as many as nine flowers on a single scape; they are white and yellow within and mauve without. *T. Alberti*, *T. lanata*, *T. Kesselringii*, and *T. Eichleri* are well worth cultivation. In mediæval times many of these Tulips were brought to Constantinople to the Caliph's garden, and from there were sent to Holland, where they were used in the production of garden hybrids and ultimately lost in their original forms.

It is evident that the next ten years will give us more new and beautiful type forms of Tulips than the last twenty-five years have done, as importations of plants from Armenia and Persia are now far in excess of anything known before; and a vast field is now open for the systematic crossing of the different species, or of the species with the best forms of garden Tulips. According to my experience with these plants, the female parent gives the form to the offspring.

Baden-Baden.

Max Leichtlin.

Seasonable Work.

THE plant-grower at this season is burdened with pressing work of many kinds. The plants intended for bedding out will naturally be among the first to be attended to, for most of them will be required during the next two or three weeks (at least in this latitude), and to prevent any check in growth after they are planted out they should be properly hardened off by abundant ventilation if they are kept in the greenhouse. The better plan is to place them in a cold frame, if such a convenience is at hand. With tender kinds, such as *Coleus*, *Alternantheras*, *Acalyphas*, *Crotons*, *Musas* and other plants of succulent growth, nothing is gained by very early planting, for the check thus given frequently results in permanent injury, and to avoid this it is wiser to keep such plants where they can be protected until the third week of May or even the first of June in exposed locations in the middle states.

The many good qualities of *Crotons* and *Acalyphas* as bedding-plants should not be forgotten, for the rich effects produced by them cannot be easily surpassed by any others. Tuberous *Begonias*, too, ought to be largely used, and in appropriate locations they will prove among the most showy of outdoor flowering plants. These should be grown into sturdy specimens before being planted out, for though the tubers may be planted while dormant and prove successful in some cases, yet a more even bed will be secured by the use of well-established plants; and the season of flowering will then extend from the time of planting out until frost comes in the fall.

In the greenhouse, also, there are many things to be provided in order to keep up a constant display. For instance, the *Gloxinias*, *Gesneras*, *Achimenes* and *Tydeas* are all valuable for summer decoration of a conservatory, and will all need liberal treatment now, such as sufficient pot-room, good drainage, a fresh light soil, enriched with liberal supplies of thoroughly rotted cow-manure.

All plants of this character should have plenty of room for the best development of their foliage; the *Gloxinias* especially need this precaution, and as the leaves frequently become a foot or more in length under good cultivation, the plants may need lifting up on an inverted pot to keep the foliage clear of the bench. Some of the Tuberous *Begonias* are excellent pot-plants for conservatory decoration, among these being *B. Boliviensis*, *B. Sutherlandii*, *B. Chelsonii* and *B. Froebelii*, all of which are worthy of more attention, and they should now be nicely started.

Caladiums also should now be started, and as soon as they become established will require an abundance of moisture both at the root and in the atmosphere to develop their finest foliage, and when the pots become well filled with roots a top-dressing of manure and also watering with liquid fertilizer will be beneficial, for *Caladiums* are gross feeders, and can assimilate large quantities of stimulating food. The *Alocasias* should now be in active growth, and, like all of the *Arum* family, enjoy plenty of moisture when in that condition. Light potting is best for these plants, and especially for the tenderer species, like *A. Sanderiana*, *A. intermedia*, *A. Sedenii* and others, and in all cases thorough drainage is essential. Seedling *Cyclamens* for next winter's flowering should now be ready for a shift from the small pots in which they have been potted off into those of three or four inch size, and these plants also should not have the soil pressed too hard into the pots, and should have a light open compost in which may be in-

cluded some pulverized brick. An airy location, with plenty of light, is necessary to insure a sturdy growth of good foliage on *Cyclamen Persicum*, and when such growth is secured there is seldom any difficulty in getting a good crop of flowers.

Pot *Chrysanthemums* for next fall will also need attention now, a steady growth being most desirable, and an essential point in securing this is to avoid all extremes in watering.

How Some Half-hardy Shrubs Survived the Winter.

NO winter, however mild or cold, passes without leaving some marked effects on the arborescent vegetation, some of which are often least expected. It is never safe to predict just in what condition any of our half-hardy trees or shrubs will come through a particular winter, because the injuries are not proportionate with the degrees of temperature registered by the thermometer. The condition of the plant when the period of rest begins in the autumn is a powerful factor in determining how much vitality there will remain in the spring, and usually sudden opposite changes in temperature are more injurious than extreme weather if uniformly cold. The past winter was, on the whole, probably a little colder than the two preceding in the vicinity of Boston. But at no time did the temperature fall much below zero of Fahrenheit, and although the ground was bare a large part of the time, there was more snow than in either of the previous seasons.

A look now over the collections of shrubs here plainly shows to what extent any of them sustained injury. *Rhododendrons* and *Azaleas* have wintered remarkably well, and very few buds show signs of injury. Even such uncertain species as *R. Dauricum* and *R. mucronulatum*, notable for their extremely early flowers, have blossomed better than usual. *Daphne Cneorum*, with the slight protection of leaves which it usually requires, appears in fine condition, although no doubt there are exposures where it has suffered. Plants of *D. Mezereum* covered with soil, and others beside them left quite unprotected, showed that there was little or no advantage this season in covering, for the unprotected plants are in quite as fine condition as the others, although the flower-buds may have been more injured by spring frosts because they developed earlier.

A Japanese *Ilex*, *I. Sieboldi*, also came through the winter in better condition by being left uncovered than closely adjoining plants of the same species which were carefully bent over and covered with soil. Some of the tips of the protected plants have an unhealthy appearance or are dead, and appear as though they had heated in the soil, whereas the unprotected plants are perfectly sound and healthy to the last bud.

The pretty-flowered *Corylopsis pauciflora*, from Japan, may be found hardy in some situations about Boston, but as it is placed in the Arboretum it does not generally survive the winters well without some sort of shelter. It forms a slender many-stemmed bushy shrub. Last autumn one-half of the stems of the plant were bent downward and covered with soil, the other half left exposed. As a result the half of the plant which was protected is now (May 4th) well laden with a profusion of its beautiful straw-colored flowers, while the ends of the shoots of the unprotected portion are nearly all dead, a large proportion of the buds are destroyed, and only a very few straggling blossoms have developed, chiefly on the lower portions of the stems.

Ribes sanguineum is another pretty plant whose branches, in this latitude, it is well to cover if good blooms are desired. Repeated experiments, similar to that with the *Corylopsis*, have shown the need and advantage of protection, and as the stems bear bending very well it is an easy matter to peg them down and cover with soil. By treating *Gordonia Altamaha* in the same way we are able, late in the autumn, to get some of the beautiful white single *Camellia*-like flowers from this southern plant.

Stephanandra flexuosa, not long since introduced from Japan, did not give promise of much hardiness when first planted in the Arboretum, but it is now well established, is about six feet high, and its buds on most of the stems appear fresh and living almost to the tips. The plant had no protection whatever during the winter.

Repeated attempts prove that, as a rule, there is not much satisfaction to be had in attempting to grow the different forms of *Hydrangea hortensis* in the open air here, if the object is to raise the flowers. In spite of heavy coverings the stems annually die to such an extent that no blossoms are produced.

The different common species and forms of *Tamarix* have come through the winter in first-rate order. Very often the ends of the branches are destroyed. The European "Gorse"

(*Ulex Europæus*) and Broom (*Cytisus scoparius*) suffered in spite of heavy covering. Neither of them is reliably hardy in this latitude and climate, although they thrive in the extreme south-eastern part of Massachusetts.

The Heaths, too (*Erica* and *Calluna*), do not always come through the winters unscathed, and even when afforded some covering a portion of the branches of *Calluna vulgaris* will sometimes turn brown. This observation is made of plants in cultivation; perhaps in thoroughly congenial situations of soil and moisture they would make a better showing. But even with a partial loss of stems, enough usually remains to produce a good show of flowers to encourage the cultivator.

Spring in Boston—A Foreigner's Impressions.

To the Editor of GARDEN AND FOREST:

Sir,—Spring came with a burst to Boston this year, as it has done a good many years, I fancy, only I have not been there to notice it. It was all new to me, and the perpetual changes in the weather were in themselves a never-failing source of interest. Watching these changes and wondering what might come next was like studying the moods of a wayward and delightful woman, whose occasional sullenness was more than compensated for by the brilliancy of her smiles, when that humor seized her, or by her impulses of stimulating breeziness. I kept a weather-journal for a while, but it took too much time even if I had been able to remember all the changes that took place when I was away from my note-book for a few hours. All of a sudden, just as I was beginning to tire of my charmer, the sovereign change came; spring was here and obliterated the very memory of all that had gone before. Spring came, with warm soft breezes that irresistibly suggested visions of southern climes, and yet helped the sunshine to fill the heart with contentment. Spring came, and with it the joy of the first sparkle of living green on the lawns of the Public Garden, the first Crocuses in sheltered places along Beacon Street. Now the whole procession of spring flowers would be coming to light up the town gardens after the long gloom of winter.

Spring in town has a beauty of its own. It may not be comparable with that of spring in the country, for all the costly bulbs that ever came from Holland cannot produce flowers which give the pure joy of the sweet English Violets, or the small star-like Anemones that spread a delicate purplish blue carpet over sunny slopes in our Swedish woods, or of the gorgeous Italian Anemones, handsome, frank and pure as a Tuscan mountain-girl. But spring in town has a beauty of its own akin to the bright beauty of the treeless south, and duly felt by the Neapolitans, among whom some of the lost Italian color-sense still lingers when they deck their fruit-stalls and fish-venders' carts with flowers in the bright colors and harmonious combinations that the glorious sunshine calls for. The call is almost as strong here in New England, and just as strong out of town as in it—witness the intense green of the Flags and the joyous note of accordance with Nature that they strike. Only in the country there are also the woods, with their broken interlaced shadows and drifted heaps of fawn-colored leaves, their expectant quietness and cold suggestive corners. In town we have nothing but unmitigated sunlight, intensified by reflection from long lines of brick walls, sharply defined house-shadow, spring dresses, bright sunshades, gay colors in shop-windows, and glittering expanses of emerald grass in plots and squares and public gardens. I do not say that there is not room for the still small voice of Violets and shady cool corners in town, too; but on the whole I think the special spring beauty of town gardens, as of fields, is mainly to be sought in brilliancy. Fortunately, Nature has provided for this, and given the artist-gardener a working palette of the most splendid colors—colors which in summer would perhaps seem garish to some tastes, but which in spring, after the long starvation of the winter, only seem to satisfy a natural craving of the eye, and afford invaluable opportunities for the education of the color-sense. Everything is educational nowadays, and such public functionaries as curators of museums and superintendents of public gardens are not always to be envied. While the democratic principle demands that they should make their collections or gardens useful for practical study by the people who pay for them, socialistic thought has progressed far enough to demand that they should feel their responsibility as educators of the masses. Now, if there is anything that needs re-educating up to a lost standard, it is the color-sense in the great mass of people to-day, and the spring

flowers offer splendid opportunities in this respect, both for strong masses and bands and splashes of pure color, represented by the Tulips, and for soft and delicate harmonies of tint and tone, furnished by the Hyacinths, so like soft uncut velvet in their first fresh texture. I have often thought that it would be well to let a French milliner with real taste be consulted about the arrangement of flower-beds, especially of Hyacinth-beds. Would that the Boston public gardener had called in a certain French milliner in Boylston Street for advice as to color-combinations! And why not? What is good in a bonnet is good in a flower-bed, and a flower-bed is a vastly more important thing than a bonnet.

My ardor of hope was a little damped when I saw that the Crocuses had been put into the lawns at regular intervals, making tedious diagonal and cross lines over the grass like the designs of certain wall-papers. Well, that was a mistake perhaps. I still ventured to hope for great things from the Tulips and Hyacinths, and made a special pilgrimage into town (I was in the country by that time) to see them.

Boston readers will appreciate my disappointment at the sight I saw. For readers out of Boston I will add that the bulbs seemed put in the ground haphazard, and that the only care exercised had been to get in as many as possible. As to color-schemes, harmonies, combinations, they were non-existent, or, at least, incomprehensible. No wonder that the ladies prefer to go to Madame O.'s plate-glass windows for their coloristic education. There was nothing educational in the bulb-beds of the Public Garden. They showed a jumble so characterless, so confused, that I could not even stop to notice the infelicitous combinations, as a warning against ever trying them again. I simply hurried on in sorrow, and now can only remember a profusion of pale mauve Hyacinths just where they ought not to be, dominating the patternless mosaic of other tints in a way that made them seem almost vulgar.

After my first impressions were in type I went into town for a second look, so that I might see the full glory of the Tulips. The Tulips were better, and some of the combinations were excellent, such as a blaze of red set off by a band of white or a field of pink, framed in a deeper rose. Some little arrangements were almost as attractive as if the French milliner's dainty taste had been consulted, as, for example, little round plots of golden white Tulips set on dark Pansies. But there were exceptions. The artist, as a rule, seems to have been controlled by the notion that a mass of Tulips in one tint or shade, set off by a border of Tulips in another and planted in a thick bed of Pansies of any color, could not help being beautiful. In some cases the result was happy, although even the little plot of white Tulips and Pansies I have mentioned would have been more effective if the Pansies had been allowed to broaden out into a border, so as to make a setting of a deep velvety tone around the bright centre of the Tulips. In other cases the result was painful—a combination of two discordant reds, for instance, or a good Tulip scheme in rose spoiled by the introduction of a bed of washed-out violet Pansies creeping between the stems.

The effect of the whole, too, was disturbing. I do not feel at all certain that the laying out of the beds is the best possible one. But given this arrangement of large flat beds, so near each other as if they belonged together, of course they ought to have been treated accordingly, and one combination ought to have led up to, or set off, the next one, and in the arrangement of the whole, which is taken in at one glance of the eye, a clear, well-thought out scheme of harmony ought to have made itself felt. Here was an opportunity for showing that the gardener is, after all, an artist of higher rank than the milliner. The Lord of Misrule had it all his own way, while the prominent note, badly introduced, was the fashionable shade of deep solferino, which requires very careful treatment to be used at all.

Bird's-foot Violets in Cultivation.

To the Editor of GARDEN AND FOREST:

Sir,—The communication from your Missouri contributor, entitled "Wild Flowers in Cultivation," in GARDEN AND FOREST for April 6th, suggests an experience of my own in the cultivation of *Viola pedata* bicolor which may have interest for others.

In the early spring of 1887 I drove from Washington with a friend to Arlington Heights. The road-side, as we ascended from the river-bank, was decked with early flowers, and as we came to the foot of a long hill, up which we were to climb, the entire slope, from top to bottom, was aglow with the va-

riety of *V. pedata* called in Washington "Wild Pansy." We had never seen it before, and the flower, with its two upper petals of velvety royal purple, seemed singularly beautiful. When we reached the Pansy-hill on our return a temptation too great to be resisted was before us. We were not prepared for gardening, but, taking off our gloves, we grubbed up the Violet-roots, which fortunately came up easily, until our pocket-handkerchiefs were filled with them. On getting back to the city we packed the roots carefully and sent them to be planted in the garden at home.

When I arrived at home, the 1st of June, the Violets were blooming in the garden, and continued to bloom at intervals all summer long. The plants were still covered with buds when the first frosts came and nipped them. Having many fears lest the cold winter should prove fatal to these natives of a warmer latitude I covered them with leaves; but when the spring came round again and the plants were uncovered, they at once began to put forth fresh leaves and flower-buds and came into bloom the 1st of May.

They are still prospering in my sunny garden, which has a sandy soil well suited to Violets. In rainy seasons they blossom all through the summer until the frost chills them in the autumn. In dry seasons there are few flowers after the profuse bloom of May until September, when they bloom nearly as freely as in the spring. The flowers are larger and handsomer than they were when the plants were first placed in the garden, and many of the lower petals are freckled with royal purple. There is no Pansy-bed near my Violets, and hybridization cannot cause the markings, for they occur on the blossoms of the original plants.

A Handbook of West American Cone-bearers: Approved English names, with brief popular descriptions of the Cone-bearing Trees of the Pacific coast, north of Mexico and west of the Rocky Mountains. By J. G. Lemmon, San Francisco. 1892.

Mr. Lemmon has devoted himself of late years to a careful study of the cone-bearing trees of the Pacific states, and in the present handbook he makes an appeal "to botanists, naturalists, school superintendents and teachers, lumbermen, travelers, and tree-lovers generally," for fixed vernacular names for these trees, urging them "to ignore senseless inappropriate names for our trees, and to insist upon suitable descriptive distinguishing names, and to have only one name for each kind of tree," which he rightly considers should be taken up by the public and made the popular name. "I am not now advocating," he remarks, "the popular use of the scientific names; that will come in due time. The youth of America will soon be ashamed not to be familiar with our principal botanical names as with household words. It will be admitted that the only really distinguishing names are those conferred and duly published by scientists having full knowledge of the subject and its relations. These are the technical names—those of last resort—for they alone may infallibly distinguish any object in nature.

"Such names, of course, are written in Latin, but they may be understood by the learned of all nations. A person often hesitates about using them, ignorant perhaps of their proper pronunciation, and dreading the burden he fears they may impose on his memory. The coining of vernacular names is a very different matter, and such names are often a matter of chance, and too frequently made without a full knowledge." As an example of this, Mr. Lemmon points to the fact that "in one short range of California mountains there are seven different species of Pine. Four of these Pines are called by the same name, and that the meaningless one, 'Bull Pine.' Now, one of these species, *Pinus Coulteri*, bears the largest and heaviest cones in the world, a single cone often weighing five to eight pounds. What better name for this tree than 'Big Cone Pine?' A second, *P. Sabiniana*, has pea-green or grayish foliage, distinguishing the trees from others at a distance. 'Gray-leaved Pine' is suggested for this tree. The third species, *P. Jeffreyi*, has dark, often black, bark, finely checkered, in strong contrast with light-colored, well-known Yellow Pine (*P. ponderosa*), with which it is often associated. What better name," Mr. Lemmon asks, "for this tree than 'Black Pine'?" He then submits what he considers the most appropriate and best vernacular names for the different coniferous trees of his region in the hope that they will, by this useful publication, become familiar to the public, and so gradually established. We are glad to publish in this connection his names, in the hope of aiding him to bring about a most desirable reform.

P. Lambertiana he would call "the Great Sugar Pine"; *P.*

monticola, "the Little Sugar Pine"; *P. Ayacahuite*, var. *strobiliformis*, "the Arizona White Pine." For *P. flexuosa* and *P. albicaulis* he suggests "Rocky Mountain White Pine" and "Alpine White Bark Pine," although this last, it seems to us, would be sufficiently well designated by the shorter name of "White Bark Pine." *P. Balfouriana* is appropriately called "Fox-tail Pine," the name by which it has been known for many years; and *P. aristata* is here called "Bristle-cone Pine."

Of the Nut Pines, *P. monophylla* is called "Nevada Nut Pine," although the species is not confined to the state of Nevada. *P. Parryana* is called "Parry Nut Pine"; *P. edulis*, "New Mexican Piñon," although New Mexico is not the exclusive home of this species; and *P. cembroides*, "the Stone-seed Mexican Piñon," a rather unnecessarily long and awkward name. *P. contorta* is called "the North-coast Scrub Pine"; perhaps "Contorted Pine" would be as good a designation. *P. Murrayana* is called "Tamarack Pine," the name by which the species, from a fancied resemblance to the Tamarack of eastern swamps, is universally known to travelers in the high Sierras. *P. ponderosa* is called "Western Yellow Pine," and *P. Jeffreyi* "Western Black Pine," the variety of the high Sierras being called "the Sierra Red-bark Pine," and that of Lower California, recently portrayed in this journal, "Peninsula Black Pine." Upon *P. Arizona* is bestowed the somewhat awkward name of "Arizona Five-leaved Lumber Pine," a particularly unfortunate designation, as the leaves are not always in fives and the species does not produce especially valuable lumber. *P. latifolia* is called "the Arizona Broad-leaved Lumber Pine," and *P. Chihuahuana* "the Chihuahuana Top-cone Pine." *P. Torreyana* is appropriately called "the Torrey Pine"; *P. tuberculata*, "the Monterey Pine," and *P. attenuata* (of Lemmon), until recently known as *P. tuberculata*, the "Narrow-cone Pine." *P. muricata* is called "the Prickly-cone Pine," and *P. Banksiana*, which Mr. Lemmon reports from the Selkirk mountains in British Columbia, "the Canada Horn-cone Pine," a name which certainly is not more appropriate or easier to fix in the memory than "Gray Pine," by which this species is almost universally known in Canada.

For the Firs, whose identity and synonymy are more confused than the trees of any other group of western American conifers, Mr. Lemmon suggests that *Abies amabilis* shall be called "the Lovely Red Fir"; *A. nobilis*, "the Feather-cone Red Fir," a name which seems to us inappropriate; *A. magnifica*, "the California Red Fir," and *A. religiosa*, "the Mexican Sacred Fir." *A. lasiocarpa* appears as "the Downy-cone Subalpine Fir"; *A. grandis*, "the Oregon White Fir"; *A. Lowiana*, "the California White Fir"; *A. concolor*, "the Colorado White Fir," and *A. venusta*, "the Bristle-cone Fir."

It hardly seems necessary to designate *Sequoia sempervirens* as "the Coast Redwood," as it is the only California conifer called Redwood, or to call *Sequoia gigantea* "Giant Sequoia." To our taste "Big Tree" is a simpler and better name. For *Thuja gigantea*, "Pacific Red Cedar" is proposed, and for *Libocedrus decurrens* "California Post Cedar." *Chamaecyparis Nutkaensis* is called "Alaska Ground Cypress," but as this tree sometimes attains a height of one hundred feet and is by no means confined to Alaska, this name will hardly find general acceptance.

Cupressus Arizona is considered distinct by Mr. Lemmon from the species of Guadalupe Island (*C. Guadalupensis*, Watson), and is here given the name of "Arizona Red-bark Cypress," but as it is the only species known to grow in that territory perhaps "Arizona Cypress" would sufficiently designate it. Nor do we like "North-coast Cypress" for *C. Goveniana*, as the species is found as far south as the shores of the Bay of Monterey, or "California Mountain Cypress" for *C. Macnabiana*—a rare and local species which grows on the foot-hills rather than on the mountains. *Taxus brevifolia* is called "Pacific Yew"—a good name, although no better than the one by which it is usually designated in books, "Western Yew."

Mr. Lemmon, following Professor Greene, discards *Torreya* and adopts the earlier *Tuminon* of Rafinesque for the California representative of a genus known in Florida, where one species also occurs, by the vernacular name of *Torreya*; and as this is now a well-established name we venture to suggest, whether *Tuminon* be universally adopted by botanists or not, that the California tree be called "the California *Torreya*" rather than "the California False Nutmeg," as is here suggested.

Such criticisms as these which we have ventured upon show the difficulty of fixing on any plant a vernacular name which will be acceptable to every one, and will serve, perhaps, to emphasize the fact that the best name for any plant is the Latin name which is given to it in accordance with a fixed and

recognized principle, and which cannot be changed except in accordance with that principle.

We are glad to see, from a notice printed at the end of Mr. Lemmon's interesting paper, that correctly labeled specimens of branches, cones, foliage, etc., of the Pacific-coast conifers can be supplied by him to museums and educational institutions at reasonable rates. His address is 1015 Clay Street, Oakland, California.

Notes.

Next year will see the tricentennial celebration of the formation of a botanical garden and the establishment of a professorship of botany in the city of Montpellier, and this event is to be appropriately celebrated there by a special session of the Botanical Society of France.

The Hard Maple of Maine furnishes a large part of the material used in the manufacture of shoe-pegs, although the wood of the Canoe Birch is sometimes used for this purpose. Shoe-pegs are sold by the bushel, and now range from seventy-five cents to one dollar a bushel, \$150,000 having been received, it is stated by a correspondent of *The Manufacturer and Builder* of this city, last year by the Maine shoe-peg factories.

We learn that the necessary steps have been taken for the formation of an American Rose Society, and it is to be hoped that this will prove a vigorous organization. It is a singular fact that the Rose receives less attention in this country than it does in many others, and there is no good reason why we should not have a flourishing Rose Society, since the growers of Chrysanthemums and Carnations have both found such associations necessary.

Cratægus mollis, which is illustrated on another page of this issue, is now in full flower in this latitude. In Central Park there are many specimens of this Hawthorn which are twenty feet high or more, and their white blossoms, appearing abundantly among the tender young foliage, make a charming picture. It is not too much to say that at this moment these trees are quite as beautiful as any in the park, which is saying a great deal, when it is remembered that both the Chinese and American Red-buds are in full bloom, the flowers of the Sassafras are just opening, and the Flowering Dogwood is almost at its best.

A large part of the spools used in this country for winding thread are produced in Oxford County, Maine, and are made from the wood of the Canoe Birch (*Betula papyrifera*), although there are in western Maine several other important centres of this industry which occupy many saw-mills engaged throughout the year in sawing up Birch-logs into strips four feet long and an inch or two inches square. These strips are worked up in the spool-factories by most ingenious labor-saving machinery, the wood being fed into one machine, and hardly seen again until it drops from another in the form of spools ready for market, except the polishing, which is done by rapidly revolving them in barrels. In some villages of Oxford County nearly every inhabitant is more or less directly interested in spool-making, and in Maine several hundred thousand feet of Birch-lumber, which a few years ago was considered almost worthless, is now being manufactured into spools.

At the April meeting of the California State Floral Society, held in San Francisco on the 8th of that month, Mr. E. D. Sturtevant presented an interesting paper on aquatic plants and water-gardening for California, which, although considered a dry country, and therefore not favorable for the cultivation of water-plants, is well supplied, at least in the cities, with water. Natural ponds and lakes are rare, although a few exist in some parts of the state, and are suitable for the naturalization of the Lotus, a feat which has already been successfully accomplished in a lagoon not far from San Diego, and irrigating ditches afford ample opportunities for supplying a garden with water. In all of central and southern California, the Lotus, of course, would be hardy, and in the southern part of the state, no doubt, all the species which are grown under glass at the east could be kept over winter without protection.

From the third annual report of the Missouri Botanical Garden Professor Trelease has recently reprinted his monograph of the species of *Rumex* occurring north of Mexico. Nineteen species are described, and the paper is enriched by twenty-one carefully drawn plates with analyses. Of the North American species one is a so-called Ballast-plant—that is, it is found only on heaps of ballast discharged from vessels arriving from foreign ports; seven others are Old World weeds; two are Arctic alpine plants of wide distribution, and eleven belong to

the true North American Flora. "The chief biological interest in the genus," Professor Trelease points out, "comes from the acidity of the Sorrels and some Docks, and the occurrence of tannin and a bitter principle in some others; their protandry and exclusive adaptation to wind pollination, and the adaptation of the greater number of species to wind dissemination by the enlargement of the inner segments of the perianth during ripening"—a peculiarity which accounts for their prevalence in cultivated ground, where they are often exceedingly troublesome weeds.

A series of fifteen lectures and field-meetings are to be held at the Arnold Arboretum during May and June for studying the trees and shrubs which grow in New England. They will be conducted by Mr. J. G. Jack, and will be held on Saturday mornings and Wednesday afternoons. The lectures will be given in the Bussey Institute, after which the class will visit the plantations and nurseries of the Arboretum for an informal study of the plants which have been under review at the lecture. The instructions will not be technical, since it is the intention to indicate by comparison the easiest means of distinguishing our common native shrubs and trees and of recognizing foreign species which have been introduced into our gardens. The ornamental and useful properties of trees and shrubs, their habits of growth, their peculiarities and common diseases will be considered, and the different plants will be taken up as far as possible in course as they become conspicuous in flowering. An autumn course of fifteen meetings will also be given, when an opportunity will be afforded for studying many of the trees and shrubs in fruit with their autumn foliage and their buds and general appearance as they prepare for winter.

In our issue for April 13th Colonel Pearson wrote that where his orchard-trees had suffered from sun-scald they were all flat-footed—that is, they had no tap-roots—and on examining the trees which had escaped the damage he found that all of them had roots which reached deeply into moist soil and sustained their vitality during surface droughts. Professor Budd quotes this paragraph in the *Iowa State Register*, and adds some examples as evidence to support the theory that sun-scald of the stem is often induced by lack of water-supply. Three years ago a Soft Maple on the Iowa Agricultural College grounds was severely pruned and its top was cut back. That season the southern half of the tree sun-scalded badly, and it is alive now only on the north side. Professor Budd has often examined sun-scalded forest-trees, and found that in each case the roots have been injured by trampling stock, so that the soil was harder and drier than in the primitive forest. The comparative hardiness of original seedling Apple-trees, which stand where their tap-roots first penetrated the earth, and trees that are grown by root-grafting with cions taken from the top illustrate the probable truth of Mr. Pearson's theory, but do not prove it.

An English correspondent of the *Country Gentleman* writes that a leading London physician has just issued his annual plea for that much despised vegetable the Stinging Nettle (*Urtica dioica*). Since the plant has become to some extent naturalized in this country, it might be worth while for some adventurous cook to try its effect on American palates and stomachs. Here is what the physician says: "In early spring-time, when sprouts and cabbages constitute the chief supply of greens, those who know the delicate value of common Stinging Nettle rejoice to find that in its hardy vigor it comes shooting up in sheltered nooks and corners almost the first among the common harbingers of spring. Its tender tops, juicy, crisp and delicate, may be cut one by one with scissors held in a gloved hand, and when a basketful is obtained—and this can often be gathered in a single corner where a heap of rubbish has been lying—a valuable and health-giving adjunct to a meal is possessed. The Nettles should be well washed, and this can be done by stirring them briskly round in a pail of water with a stick, or by putting them under a running tap, and then put into boiling water. In about a quarter of an hour their stinging power will have disappeared, and they will be like very delicate Turnip-tops. They may be served in many ways, but perhaps one which will be found specially palatable is to treat them like Spinach and serve them on toast with a poached or fried egg. If Londoners would only ask for nettles, nettles would soon be found in the market, and a vegetable which is now the farmers' and gardeners' pest would prove a source of profit. Nettles are especially valuable for their diuretic and antiscorbutic properties, and would be found far more helpful in purifying the blood than the concocted 'blood mixtures' so persistently puffed and widely used."

The Preservation of Natural Scenery.

MORE than two years ago Mr. Charles Eliot called attention, through these columns, to the fact that within ten miles of the Boston State House there were several surviving fragments of the primitive New England wilderness, which possessed uncommon beauty, and more than usual refreshing power. One of these was the steep moraine of Waverly, set with its group of mighty Oaks; another was at the upper falls of the Charles River, where its rugged banks are covered with dark Hemlocks. Two others were groves of great White Pines, the tree which the forefathers of New England blazoned on their flag, and another was a bolder-strewn hillside which commanded a distant view of the ocean. Scenes of this kind in the older portions of our country are rapidly disappearing before the axe and fire, and carelessness of visitors and campers whose destructive invasion soon robs them of all their poetic charm. Mr. Eliot suggested that some association should be formed to protect places of this sort, and he argued with force that while lovers of art in great cities had shown themselves willing to found museums where select works of painting and sculpture were kept for public exhibition, lovers of nature who felt that natural scenery supplied a pure and elevating enjoyment as well as an education in the love of beauty, which was at least as valuable as that afforded by cast or canvas, might well unite in rescuing from destruction these choice bits of scenery so that they could be held secure for the delight and instruction of successive generations. The national Government has recognized the force of sentiment in this direction by setting apart the Yosemite Valley and the Yellowstone Park, and by empowering the President to reserve certain forest-areas as public possessions forever. By special enactment the state of New York has acquired possession of Niagara Falls, and by another special act Chittenango Falls has been protected from destruction and vulgarization. But we argued then that isolated efforts

would avail little in comparison with organized association, and finally some public-spirited citizens of Massachusetts prepared a plan which has since then been embodied in a state enactment. From time to time we have given reports of the progress of this movement, and we have now received the *First Annual Report of the Trustees of Public Reservations*, which furnishes strong ground to hope that, as the machinery of the law is understood, the intelligent and patriotic people of that state will see to it that many scenes of natural beauty and historic interest, now endangered by private occupation, will be rescued and dedicated to public use forever.

The act incorporating the Trustees of Public Reservations enables them to acquire and hold by gift, purchase or otherwise such real estate as may be worthy of reservation and to keep such property open to the public. According to the report, Massachusetts is shamefully lacking in spaces reserved for enjoyment by the public. The cliffs and beaches of the seashore, the mountain-tops of the interior and almost every scene of special beauty in the state are passing into the ownership of persons who hold them for their private pleasure or for the profit which may be reaped from fees collected from visitors. As the population grows, the destruction of the most beautiful passages of scenery which remain will go on more rapidly, so that the committee did well in the beginning to explore the field and secure some definite information as to the actual situation. Mr. J. B. Harrison was engaged to go through the seashore townships of the state and to discover to what places on the shore the public had a right to resort and what further provision was needed in this direction. The interesting letters from Mr. Harrison, which were published in this journal last year, are reproduced in this report, and we need not repeat the story of public holdings which have been assaulted and invaded until over a large portion of the coast there are few places of any kind to which the people can repair without the danger of being arraigned as trespassers. It is to be hoped that this work of examination will be extended throughout the state, so that a record can be made of all the beautiful and memorable places which it will be advisable to secure as public property. As it is, many other places which are notable for historical or literary associations or romantic beauty are mentioned, and the hope is expressed that this permanent Board of Trustees will find means to secure and protect them.

The first actual gift to the Trustees is one by Mrs. F. H. Tudor, of a diversified tract of woodland of some twenty acres in the south-eastern part of Stoneham. This is situated so that it will serve as a delightful retreat for a large population in a thickly settled district. A second proposal comes from a gentleman who expresses his desire to present one of the most interesting groves near Boston, and to give it into the keeping of the Trustees in memory of a young man who had a singular love for all natural beauty. The committee believe that, in the future, there will be many interesting examples of natural landscape preserved in *memoriam*, and it certainly is a beautiful idea to have a living landscape religiously guarded for this purpose as a monument much more impressive and enduring than any work in marble or stained glass. A third suggestion comes from one the name of whose ancestors is permanently attached to a picturesque situation, which will make a useful and handsome public reservation. There can be little doubt that many other places identified with honored names can be found which can be permanently preserved under the care of this Board.

Altogether, the formation of this Society and the energetic and broad-minded way in which its work has begun are most encouraging, and too much credit cannot be given to the originators and promoters of the movement, and especially to Mr. Eliot, who seems to have been most active in the enterprise. The single fact, that a way has been opened for securing places of recreation and assembly for the throngs in the rapidly growing cities and towns of Massachusetts, is of itself a matter for congratulation.

But of still greater importance is the fact that the refreshing and uplifting influence of natural scenery is recognized as an actual and practical truth. The humanizing influence of historic association may well be coupled with the soothing and healing charm of natural scenery, because neither of them appeals directly to any sordid or purely material interest, but to our nobler impulses and passions. The home of Washington, the winter camping-ground at Valley Forge, the beautiful old colonial mansion and grounds at Morristown, which was once the headquarters of Washington, address the same class of emotions as do the Natural Bridge of Virginia or the Big Tree-grove of California. They all minister in their degree to the mental and moral health of communities. In this country there are no remnants of royal hunting-parks for popular resort, and few public footpaths even which lead across private lines. As a nation our life has been so short that places of historic interest are few compared with those in the Old World; and broad as is our national domain, the scenes of natural beauty which are not private possessions are more rare than they are in countries with a much denser population. This Massachusetts movement ought to be contagious, for there are few states in which a special act of the Legislature is not needed whenever any land is acquired for public use. Of course, there must be a commanding public sentiment behind any act like this one creating the Board of Trustees of Public Reservations. As the report sets forth, the function of this Board is "to facilitate" the preservation of beautiful and historical places, and the appreciation of the value of such places, and the desire to secure them, must precede and make possible any action of the Board. When this sentiment comes in the fullness of its power it will not only manifest itself by securing and protecting by law a few tracts here and there, but it will be seen in a reverent regard for natural scenery over the entire face of the country. It will ensure not only intelligent treatment of these reservations, but it will help to protect every pleasing prospect from being marred, and it will act as a sensitive public conscience to protest against the obliteration and defacement of natural beauty and the desecration of spots that are hallowed by historic memories wherever they are found.

"EVERY one who has encouraged or even permitted the natural growth of his filial love for mother nature loves trees. Occasionally some such son or daughter has been carried so far by this fondness as to learn something about our trees and to know them for their own sakes, and many more have wished for some royal road to a knowledge of them. Some of these may be glad of the assistance of definite information concerning just what trees grow within easy walking distance of their homes, and just where such can be seen."

These sentences are from the introduction to a series of papers on Amherst trees which Mr. J. Ellis Humphrey is to contribute to *The Amherst Record*, the first part having appeared in its issue of the 4th instant, and it is this sort of assistance which the author proposes to offer to his fellow-townsmen, and to give them an annotated directory of the species of trees to be seen within a radius of a mile from the post-office of Amherst, Massachusetts, after the fashion of the papers originally contributed by Mr. John Robinson to *The Salem Gazette*, and lately published by the Essex Institute in a volume entitled *Our Trees*. Of Mr. Robinson's work we have spoken more than once, and we are pleased to notice that an authority of such rank as *Nature*, after stating that the book makes no pretense of being a scientific treatise, adds that "it is a series of homely chats about trees by one who knows and loves them, and, therefore, by one who cannot help telling you something worth learning, even though it be by the way and merely incidental."

The multiplication of these popular essays about our trees is a hopeful sign. It is surprising how little most

persons really know about the trees among which they have lived from childhood, and almost everybody would be grateful for some accurate information concerning them. If there are people so unfortunate as not to care to know about nature, it is possible, perhaps, to arouse their slumbering senses and to invigorate their faculties by pointing out the beauties and the uses of natural objects, of which, for this purpose, trees are the most available, as being almost everywhere present, of large size, picturesque appearance and general usefulness.

The more people, and especially the more children, there are in the United States who have learned to know and love and respect trees, the better it will be for the future of the nation. Our prosperity is dependent on the preservation of our forests. A forest is only an aggregated mass of trees. When we come as a people to know and appreciate and love trees we shall learn to love forests, too; and once loving them, we shall appreciate their value, and efforts to preserve and maintain them and make them useful and productive for all time will then be a comparatively easy task. But to do this a whole generation of Americans must be educated. The lesson must begin in the cradle, and it must continue year after year until our people love trees and know their value as well as they know the Constitution of the United States and their rights as citizens. It is for these reasons that every addition to our knowledge on this subject is valuable, and we therefore welcome the appearance of such papers as these Mr. Humphrey is publishing, and which we hope later to see gathered together in a handy volume which will serve as another text-book for the people of New England.

American Conifers in Scandinavia.

OUR correspondent, Dr. C. E. Hansen, of Copenhagen, who has charge of one of the richest collections of coniferous plants in northern Europe, sends us the following notes relative to certain American species in Scandinavia:

Sequoia gigantea has been tried in Norway in several places along the coast between Christiania and Molde in latitude 62° 44" north. In the botanic garden at Christiania a specimen six feet high when planted stood for several years, always losing in winter the growth of the previous season, so it is not probable that it will prove hardy there. In a garden at Balestrand a *Sequoia* about three feet high was planted in the spring of 1876; in the severe winter of 1880-81 the leader was killed back, although a new one was afterward formed, and in September, 1885, the tree had attained a height of seventeen feet and ten inches. In south-western Sweden the *Sequoia* seems hardy, although it is probably not to be found farther north than latitude 57° 42".

Thuja gigantea occasionally suffers from cold at Stockholm, but *T. occidentalis* is hardy at Upsala in latitude 59° 52" north; on the west coast of Finland it can be found as far north as 63°, and is said to grow as far north as 65° 51". *Taxodium distichum* is not hardy in southern Norway, and in Sweden it is rare and probably is not cultivated farther north than the southern part of the kingdom. Dr. Schuhueler, in his *Viridarium*, says of *Abies Fraseri*, that he has never seen this species anywhere in Norway except at Molde, in 62° 44" north, and in the botanic garden at Christiania, where formerly there were two plants. The tallest of these died in the summer of 1881, its roots having reached the wet subsoil. This specimen had produced good seeds for a number of years and was forty-five feet high, with a spread of branches of thirteen feet on the ground, and was forty years old. In Sweden this species is hardy at Stockholm, and is probably hardy in St. Petersburg.

In southern Norway plants of the Douglas Fir (*Pseudotsuga taxifolia*) may be seen fifty feet in height. In Sweden it is hardy at Stockholm, as is *Pinus rigida*. *Pinus Strobus* has been planted in many places on the coast of Norway up to latitude 63° 26" north, where it is hardy, and it may be expected to thrive even farther north. The largest plant in Norway is near Christiania, at Bagstad, and is about one hundred years old. This plant is eighty feet high, with a trunk circumference of more than six feet. Near Stockholm, in the park of the royal castle at Drottingholm, several fine specimens of this species are found. When I visited these trees I did not take their exact measurement, but observed that my arms would

not reach more than half around the trunks. Other specimens of this tree, all of about the same size, are to be found in Norway.

Pinus Jeffreyi has not been tried in Norway except in the botanic garden at Christiana, where there is a specimen fifteen years old and six and a half feet high. In Sweden this species is hardy in the south, as it is at Stockholm and at St. Petersburg. *P. ponderosa* is hardy in Sweden at Alwarp and at Gathenbourg. *P. cembra* grows well in southern Sweden, and in the vicinity of Stockholm increases in height at the rate of more than a foot a year. *P. Laricio Austriaca* is occasionally planted in Norway in the neighborhood of Christiana and occasionally as far north as 68° 12' north, where for a number of years it has proved hardy. The largest specimen I have seen in Norway stands in the botanic gardens at Christiana. It was planted in 1842 when it was a foot high; it is now thirty-eight feet high, with a trunk four feet in circumference. It has also proved hardy in the neighborhood of Stockholm and in Finland.

Quaker Burial Grounds.

THE final resting-places of the Society of Friends show the same severe and simple taste which characterizes their homes and ways. Repose and quiet are the keynotes of their well-ordered lives, and restfulness pervades the unadorned grounds where the plain people sleep their last sleep. The original custom was to have no stone to mark the grave of a member of the Society; and not even a mound to indicate the spot where a dead Friend was laid. Records of locality were, however, kept by the meeting, so that a man could know just where his family was interred.

There are some old burying-grounds in Pennsylvania where there was formerly only a plain stretch of greensward with a few trees, but for the last fifty years the custom of putting small stones to mark the burial spot has prevailed. In a very old ground at Abington, Pennsylvania, I found no stone earlier than 1840, showing that before that time they were not used, while rows upon rows of mounds, unmarked, showed where the earlier forefathers of the hamlet lie unchronicled. In another old grave-yard in Philadelphia itself, at Seventeenth and Cherry Streets, there are but few stones, and scarcely any signs of graves. Groups of trees and shrubs shade the enclosure, and the grass is green in this ancient spot, and dotted with small wild flowers. Around it circle brick walls of buildings, but the yard itself, which occupies a city square, is verdant and secluded. Many of the dead have been removed from this spot to larger suburban cemeteries, but some sunken stones still show where others lie undisturbed, and the turf is growing over many an unindicated grave.

The stones themselves in this, as in the other grounds I visited, are about eighteen inches wide, and but six or eight inches high. Upon the sides, sometimes upon the narrow upper edge of the stone, are chiseled the name of the deceased and the day and year of birth and death. On one stone only, among all that I saw, was there any other inscription, and that was a pathetic line from a heart-broken wife. On one other modern stone was the tiny reclining figure of a boy reading, the memorial of a deeply mourned son; but these were the only departures I observed from the plain severity of the rule.

There is a dignity in this quiet and unostentatious treatment of the dead which appeals to the mind as worthy and befitting. No "storied urn and animated bust" here records the fame and glory of the sleeper. Dust they are, and unto dust they return, and their little lives leave no haughty record of achievement. Peaceful are these old grounds, with their formal lines of trees, their unobtrusive stones, their stretches of green grass, and the quiet old meeting-houses standing beside them. The Abington meeting-house is situated in a fine grove of Oaks and Maples, somewhat disfigured by the unsightly sheds that serve to shelter the carriages of the worshippers, and through this we pass into the stiff enclosure behind the building, where the dead Friends are laid under the branches of spreading trees in silent array. Beyond the highway rise the great woods of Alverthorp, which add to the seclusion of this retreat from the world.

Another day I strolled up the quaint main street of Germantown, bordered with venerable houses, and found my way to the old ground that lies behind and around the orthodox Friends' meeting-house. Here are more overshadowing trees, and some of the graves are overgrown with English Ivy that has straggled from the wall and covered them with a dark green drapery, that must be put aside to read the names upon the gray and blackened marble. Wild flowers bloom here unmolested amid the turf, staring it with timid color. It was

the close of the Fourth Day Meeting, and groups of men in broad-brimmed hats, and of women in close gray bonnets, were emerging from the old stone building and softly wending their way homeward, with friendly hand-shaking and quiet words to each other. The girls and boys of the Friends' school were playing gayly in the sunshine, unchecked by the neighborhood of the dead. New houses stand unseparated, even by a fence or wall, from the burial ground, so that their groups of trees seem to form a part of it. As I came back I looked in at the windows of the old place of worship, where I have often sat in former days, and saw it still the same. The whitewashed walls, the rows of unpainted benches with gray cushions, the raised gallery for the preachers and elders of the meeting, the well-known air of cleanliness and quiet, of silence and recollection—all as of yore. The breeze was soft and spring-like, the birds caroled in the overhanging branches, the voices of children rang in the air, the dead slept peacefully outside, and I thought with tenderness of those beside whom I had sat in this venerable sanctuary who now lie beneath the sod, while their hallowed memory lives with a younger generation, perhaps straying from the simple and austere faith which, having fulfilled its mission, by preaching equality and liberty and the soul's direct communion with its Maker, is passing away from among us—the more's the pity, since the noble lessons of self-restraint, of order, of tranquillity of mind, of patience and simplicity, which its believers preached in word and life can never be outworn. The trouble is that it is a religion for the saint rather than the sinner, and demands the elect rather than the rank and file of struggling humanity for its members, and hence is little suited to a roystering world that desires praise, and noise, and glory, and a flaring record of life upon its tombstones.

As I passed, on my return, a modern cemetery crowded with monuments of unequal heights, with shafts and obelisks, and cenotaphs and sarcophagi in dire confusion, the ground splotched with gaudy flower-beds and blazing with color, I thought how much nearer to beauty was the idea of the Society of Friends, to whom a burial ground was a solemn lesson, not a spot for showy adornment, whether of marble or of herbage, but one where repose and silence should prevail, and no temptation to idle curiosity mar the serious scene.

Surely in the home of the dead there should be quiet and restfulness, rather than hubbub of color and violence of form, and we may well learn a lesson in taste from those who, believing in an unchanging fashion, mark the spot where lie the remains of those they love with the simplest record, the most unobtrusive head-stones, and write an epitaph only in their own faithful hearts.

Ingham, Mass.

M. C. Robbins.

Notes of a Summer Journey in Europe.—XV.

AFTER a week spent in the Jardin des Plantes its treasures can hardly be said to be more than glanced over, but where one has only two weeks to devote to the botanical and horticultural places of interest in and about Paris it is well to give some of the time to an examination of collections and institutions outside of the Muséum. Among many others, the park of the Petit Trianon, the favorite garden of Marie Antoinette, is likely to prove satisfactory to the admirer of fine trees and natural beauty. Many of the botanical treasures collected by the elder Michaux in North America were first brought here to enrich the Queen's garden. The gardens of Versailles, as a whole, may be more interesting to many persons than this little corner of it, but the formality of the great gardens of the palace, masterpieces as they are called, proved tedious and uninteresting to me. This is or was, beyond question, a great work, and withal an enormously expensive one, a work which probably contributed its small share in bringing about the Revolution. In its imperial days, too, when maintained in immaculate order, it no doubt seemed a very paradise to its frequenters. But, apart from its present partial neglect, how dreary and monotonous the gardens, formally clipped trees and straight-cut vistas seem to-day. The dry fountains, straight-edged canals, the geometrical figures and similar arrangements are a weariness to the eye, and one's sympathy goes out to the lines of trees, seen everywhere in the vicinity of the palaces, which, we are told, are cut and clipped in order to harmonize with the style of architecture of the buildings. Little wonder that Marie Antoinette preferred her "English garden," as she called it, and the park of the Petit Trianon for an occasional secluded retreat.

In the immediate vicinity of the little palace or château, on the side adjoining the Grand Trianon, the French or formal style of gardening prevails, and it is behind this that we find

the more secluded and beautiful tract which was laid out as the "English garden." Almost every visitor to Paris goes to Versailles, but after a weary pilgrimage of sight-seeing in palaces and show-grounds few get beyond the edge of the Petit Trianon. The picturesque dairy, boudoir and pavilion, built more than a century ago, now show unmistakable signs of deterioration and decay, but, with few exceptions, the noble trees remain in fine health and vigor. A Lombardy Poplar, which a label tells us was planted by Marie Antoinette in the reign of Louis XV., was broken by the wind in 1880, and now has only one green spot left on the side of its trunk. This little remnant is kept alive, and in connection with the roots, by a narrow living strip a few inches in width. The remainder of the trunk, six feet in diameter in its widest part, is quite denuded of bark and so decayed and hollowed out that only a mere shell remains. Cedars of Lebanon, *Zelkova crenata* and *Sophora Japonica* are among the best examples of introduced Old World species of trees in the park. It is said that the *Sophora* does not mature fruit here.

Through the industry of many of the early botanical explorers and collectors North American trees have a fine representation in the collection; in fact, this is probably one of the best places in France to see certain species. Here may be seen fine rugged old specimens of *Sassafras* and of Ash-leaved Maples, and vigorous trees of the Bitter-nut Hickory, *Hicoria minima* (*Carya amara*). The common *Catalpa bignonioides*, said to have been planted in 1726, is two feet in diameter, while our North American Red Mulberry (*Morus rubra*) has a trunk nearly as large and is a broad-spreading specimen, whose age is attested by its moss-covered limbs.

A Tulip-tree, to which a label is affixed bearing the date of 1663, is a fine example of this species, having a trunk two and a half feet in diameter; a Red Oak, said to have been planted just two hundred years ago, has a stem three feet through, and trees of the American Linden have attained fine proportions. They are, however, very much affected by Mistletoe, which causes irregular knots and swellings on the branches and limbs. Its effects at first give the foliage a sickly appearance, and later often causes the death of the affected limb. Great globular masses of the Mistletoe also seriously infest some of the large Poplars, but *Catalpas* and some other kinds of trees in the vicinity appear quite free from the parasite.

The visitor here has an excellent opportunity to study "knees" of the Bald Cypress (*Taxodium distichum*) of our southern swamps, of which there are some very handsome tall and thick-stemmed trees, said to be over two and a half centuries old. The trees being planted in the vicinity of a pond or lakelet, a part of its margin has become thickly studded with the "knees," which are of very various shapes and from one to three feet in height. I was surprised to find these peculiar growths extending so far from the trees, in some cases being distant from ninety to one hundred feet. The theory that these knees act as a support to the tree in yielding soil (*GARDEN AND FOREST*, vol. iii., p. 21) would hardly apply here, where they are comparatively slender and extend so far from the base. In drained portions of the ground the knees are noticeably very small.

Examples of our White Pines, with trunks four feet in diameter, and Douglas Spruces sixty-five or seventy feet high, attest the suitability of soil and climate in this locality to these favorite American conifers. The Red Cedar, or Savin (*Juniperus Virginiana*), exhibits various familiar forms or outlines, and we find old trees with their characteristic spreading and straggling habit and younger specimens of the more regular close pyramidal form, such as we commonly see in New England. Good examples of various species of Spruces, Firs, Hemlocks, Sequoias and other conifers might be enumerated.

The garden and nursery adjoining the park is quite worth a visit, and such old acquaintances as *Dirca palustris* and *Kalmia latifolia* are found to be represented by as fine rugged old specimens as can be seen anywhere in cultivation. Here, also, we find the true *Magnolia macrophylla*, a rare tree in European collections, those passing under the name sometimes proving to be our *M. tripetala*, or Umbrella-tree.

Arnold Arboretum.

J. G. Jack.

Early May in West Virginia.

FORSYTHIAS are now out of bloom, and so is the delicate and graceful little *Spiræa Thunbergii*. Their places are taken by the Japan *Corchorus* and some of the later *Spiræas*. Large clusters of these shrubs are mingling their flowers in the garden, and mask the foundations of the house effectively.

Both the white and the pink flowering Almonds are now in perfection of bloom. These shrubs never grow very tall, four

feet being their average height at maturity, and a group of three varieties, the white, the pink-flowering and the striped-bark Almond, are exceedingly pretty against the stone foundation of a country-house. Their suckers should be encouraged to grow and the pruning-knife used judiciously on the old wood to prevent the straggling appearance they are apt to assume in uncared-for old age. The ground about them should be kept mellow, and they ought to be mulched for winter protection, as they are not perfectly hardy. They well repay a little care by the extreme beauty of compact specimens when covered with their early bloom.

Wistarias are now clothing the trunks of their supporting trees and draping their branches with festoons fringed with clusters of purple flowers. With us these lovely vines seem to have alternate seasons of scarcity and profusion. Last year they gave us very few flowers, for which they are now atoning by a luxuriance which is delightful to the eye. They grow with amazing rapidity, and soon reach the tops of tall Locust-trees. The foliage of these trees does not give a dense shade, but just furnishes the shelter from the sun which Wistarias seem to require, as they bloom before the Locusts which they climb are in full leaf. Later in the season the tree and the vine mingle their blossoms with an indescribably beautiful effect.

One of the earliest shrubs in flower of the great family of Leguminosæ is the Chinese *Caragana* (*C. Chamlagu*). This is now blooming in a section of a shrubbery where many of its relatives are planted. Its small, glossy, dark green, pinnate leaves are so delicately beautiful, and its flowers are so large and showy, that it is a most attractive plant. When the blossoms open they are a clear yellow, but a few hours' exposure to the hot sun changes them to orange and brown, and they have almost the same range of color with the old-fashioned Wallflowers, one of the old plants beloved by our grandmothers. These are now in full bloom, and carry the memory back to days of childhood, when they were first known and loved.

Flowering Currants have bloomed abundantly this year, but are now fading. The numerous varieties of *Cydonias* are all so useful and pretty that it is hard to select a favorite. Between the charms of the various-named varieties in different tints of scarlet and orange one hesitates to choose. But the lovely white *Cydonia*, known as *Simplex alba*, captivates every beholder. This variety is perhaps most effective when planted close to one of the deep red sorts, though a clump of them standing alone is a very beautiful sight. *Gaujardii* and the other orange-red varieties are best by themselves, and are now strikingly handsome, blooming even more profusely than usual.

The buds of *Magnolia Lennei* were much injured by the severe frosts of April, and our one specimen of this tree did not produce a single perfect flower. The winter and late spring have been peculiarly trying to vegetation, and a fine *M. cordata* was killed outright, while a small Evergreen *Magnolia* safely housed under a barrel did not seem to suffer at all.

Staphylea trifoliata makes a pretty little tree about ten feet in height, and is a native of our woods. It is now profusely ornamented with raceme-like clusters of curious white flowers hanging from the ends of its branchlets, and which will soon be followed by large bladderly pods, which have given it its common name of Bladder-nut. It improves greatly under cultivation, and a specimen we brought from the woods two years ago has flowered more freely and grown more luxuriantly, and in more symmetrical form, than its wild relatives. *S. Colchica* is about a week later than our native plant, and is now in bud. It is a neat compact little shrub with glossy leaflets and very fragrant white flowers, much prettier than those of the American variety, which has little or no perfume.

Nevusia Alabamensis is showing a few first blossoms. These flowers dispense entirely with corolla; they have five green sepals and very numerous white, yellow-tipped stamens, and are produced so freely that they completely mantle the bush, and have a most dainty and feathery effect. The shrub is a rapid grower. Last year, in spite of the severe drought, it made very satisfactory progress, and threw up a root-sucker six feet in length. It is of the easiest cultivation, and is especially interesting to botanists from the fact that it is found in but one locality in Alabama.

The Red-bud and the large-flowering Dogwood are now the most conspicuous of our native trees. They are very often found growing, side by side, in the woods here, where they form a beautiful illustration of Nature's skill in grouping for effective contrast. Many copses of Red-bud have for background the delicate young foliage of Oaks and Hickories, and form a lovely fringe to the borders of deep woods. A large-flowering Dogwood, planted by itself in rich ground

where it can develop evenly on all sides, is one of the best of small trees. In such a situation it forms here a spreading tree twenty feet in height, and is now so covered with bloom that it appears to have profuse white foliage. Near it is planted the red-flowering variety, our specimen being at present about eight feet in height. The original red-flowering Dogwood came from Virginia, but trees whose flower-bracts vary from pure white are not rare. A fine specimen grows near us on the banks of the Potomac, and I have seen another in a distant

name an appropriate one. When a plant receives a common name it is a sign that it is becoming well known and loved, and no shrub of recent introduction is worthier of popularity than the graceful *Exochorda*. It is said to be short-lived.

Evergreens have suffered from the late frosts, and Peach-trees are giving very little bloom. Apples and Cherries and Pears promise an abundant crop.

In the wild garden Anemones, Trilliums, Columbines, *Mertensia Virginica* and *Phlox divaricata* are now most conspicu-

Fig. 42.—*Menispermum Dauricum*.—See page 234.

wood. The bracts are not pretty or showy until fully developed, when they gradually assume the pink of the Wild Rose.

The Japan Red-buds are showing very scanty bloom. Possibly, in the struggle for existence during the drought of last year, they had no vitality to spare for the formation of blossom-buds. They do not seem to be as hardy here as the native variety. *Exochordas* are flowering well. The common name for this shrub is Pearl Bush, and the round buds strung along the stems have a pearly whiteness and purity which make the

ous. The latter plant is very charming when given a little care. It needs partial shade, and is exceedingly pretty at this season, having a wild grace of its own, making it more attractive to a lover of untamed nature than any of its more cultivated relatives.

The garden is gay with bloom and musical with the songs of many birds, and, altogether, the old earth, in its renewed spring freshness, never seemed a more pleasant dwelling-place.

New or Little-known Plants.

Menispermum Dauricum.

THE genus *Menispermum* contains two species which so closely resemble each other that they can perhaps as well be taken for geographical varieties as species. The origin and type of the genus is a native of our northern states, where it is not rare on the banks of streams and in other low, moist situations; the second species, of which a figure is published on page 233 of this issue, is Asiatic, and appears to be common and widely distributed in Siberia, Manchuria, northern and central China, and in Japan. Like its American relative, it is a graceful woody climber, with slender stems which attain a height of eight or ten feet, but the leaves, which are thin and membranaceous, dark green and opaque above and pale below on both the American and the Asiatic plants, are on the latter often more deeply cordate at the base and less deeply angled. In their size and general appearance, however, as well as in the character of the flowers and fruit, the two plants are hardly to be distinguished. Both take kindly to cultivation, and are useful plants for covering small trellises or low screens, stumps or walls, although they make rather a heavy, solid mass of foliage, due to the interlacing of the delicate stems which wind one around another and do not reach out for other supports and so break up the pyramidal outline they form in growing. Both species are hardy in the northern states, and, in cultivation, produce an abundance of their handsome black fruit, which, although hidden under the leaves until these fall very late in the autumn without changing color, is more showy than the small long-stalked clusters of minute yellow-green flowers.

Plant Notes.

Some Recent Portraits.

THE colored plate in a recent issue of *The Garden* is devoted to a group of the hybrid Java *Rhododendrons*, of which a correspondent writes in the columns of our contemporary that "few, if any, greater triumphs of the hybridist could be pointed out than the magnificent forms of Java or tube-flowered *Rhododendrons* that are now to be found in our gardens, with which the name of Messrs. Veitch is so closely connected."

The first of these hybrids, known as Princess Royal, was raised about forty years ago by crossing the white-flowered *Rhododendron jasminiflorum* with the orange-flowered *R. javanicum*, the offspring producing pink flowers. This, the type of the race, is still one of the best of its color, and none of the more recent acquisitions surpass it in habit, foliage, or in the abundance of its flowers. Other species have since been used in the establishment of this garden-race, which now contains the blood not only of the two species mentioned, but also of *R. multicolor*, *R. Brookeanum*, *R. Lobbi*, *R. Malayanum* and *R. Teysmanni*. The offspring of these crosses produce scarlet, pink, yellow, white and rose-colored flowers, and the plants have the merit of remaining in bloom almost continuously throughout the year, provided they are subjected to a sufficiently high and moist temperature. They are not, however, very vigorous plants, and their habit often leaves much to be desired. Most of these hybrids produce single flowers, although among them is a small group with double flowers, to which the name of *R. balsamineflorum* has been given, from their fancied resemblance to the double *Balsam*-flowers. This double-flowered race originated from one bloom, which showed a tendency to make a double corolla, and which, being fertilized with its own pollen, produced seeds from which the double-flowered plants were raised. They are distinctly inferior to the single-flowered kinds in beauty, although they last much longer.

The writer of *The Garden* recommends the following varieties: *Luteo-roseum*, *Primrose*, *Jasminiflorum carmina-*

tum, *Duchess of Edinburgh*, the *Prince Leopold*, *Princess Royal*, *Duchess of Teck*, *Militaire*, *Aphrodite*, *Princess Christian*, *Brilliant*, *Favourite*, *Lord Woolsey*, *Princess Alexander*, *Queen Victoria*, *Triumph* and *Ophelia*. All of these and many others may be found in some of the best American collections, notably in Mr. Hunnewell's garden at Wellesley, where the cultivation of all *Rhododendrons* is made a specialty; and apparently they thrive in this country and give as much satisfaction as they do in England.

A Double-flowered Cyclamen.

AMONG the so-called garden varieties of plants those with double flowers often attract attention. These flowers are not only in many cases handsome, but often they have some interest to the students of botanical science. This character of "double flowering" is, however, attributed to different forms, in which a development of supernumerary organs, such as petals, has taken place. But there are recorded instances in botanical literature of other organs thus developed, especially in Masters' *Vegetable Teratology*. There may, then, be a distinction made between the cases in which an augmentation of parts of the flower has taken place as a result of overdevelopment, the affected organs being repeated over and over again, often without any transmutation of form, and other cases which ought more properly to be classed as examples of proliferation of the flower.

It does not seem to be common for both of these forms to occur on the same individual, yet it has lately been observed in a specimen of *Cyclamen Persicum*, which is cultivated in the United States Botanical Garden. All the flowers were abnormal and somewhat larger than in the ordinary form. In some of these, as shown in Fig. 43 (p. 235), the number of corolla-lobes was increased to eleven, but they all showed the typical form and color, light rose with crimson base, and were distinctly arranged in wreaths, so that no fission of the lobes seemed to have taken place. It was a case of simple multiplication of the corolla. The calyx was perfectly normal, but the number of stamens was increased to seven or eight, which, however, like the pistil, did not show any kind of transmutation of form.

Some other flowers of the same individual were, on the other hand, proliferous. There were developed here, inside the calyx, small whitish flowers, more or less distinctly situated in the axils of the five calyx-lobes and between these and the lobes of the corolla (Figs. 44 and 45). In these proliferous flowers the number of corolla-lobes was seven or eight, situated in wreaths, as in the flower described above. The calyx-lobes, the stamens and pistil did not differ, however, from the normal form.

If we examine one of these small flowers (Fig. 46) which has been removed from the specimen illustrated in Fig. 45, we see that there is no calyx, and that the very irregular corolla has eight separate lobes which are not distinctly arranged in spiral, and are not bent backward as in the normal corolla. These small supernumerary flowers were merely in bud, while the main flower was in full bloom, and the stamens and pistil were merely present as rudiments.

Winter Protection in Mild Climates.

I HAVE been much interested in some experiments in protecting tender and half-hardy plants. In this climate the rhizomes of many *Cannas* will usually pass through the winter in the ground without any particular protection. This is particularly true of *Canna flaccida*, which is rapidly becoming a weed by running under fences and invading neighboring grounds. Those varieties which make very stout and short rhizomes of a more fleshy character are liable to be injured unless covered. *C. Ehemanii* keeps much better protected in the open ground than it does lifted, as its rhizomes will not endure drying as others will, and if lifted it must be put into a greenhouse and some degree of growth kept up. In the open ground it comes through in fine condition when covered with coarse manure or with sawdust. The *Crozy Cannas* came through with the same kind of protection.
